CSR and Data Protection

Kadir Atilla Toker
Norwegian University of Science and Technology
(NTNU), Trondheim, Norway

Synonyms

Data care; Information protection; Information security; Preventing information misuse

Definition

Data represent facts and concepts in a formalized manner suitable for processing and interpretation by humans or automatically. Data protection refers to the prevention of data misuse, particularly information about individuals (Toker 2015, p. 169).

Corporate Social Responsibility (CSR) is a business-related terminology that encourages companies to take responsibility for the impact of their activities on various stakeholders and the society at large. Data and information are both valuable content in this regard while data protection and privacy are controversial subjects in the CSR agenda.

Introduction

The various definitions of data mostly describe it as “sensory stimuli that we perceive through our senses,” “representing unstructured facts,” “facts about unidentified entities” (Bercic and George 2009, p. 192), “collected facts from observations or recordings about measurable events, objects or people,” “recording particular instances of reality” (Checkland and Holwell 1998, p. 171). According to these definitions, data acquire meaning only when processed by a human recipient, after which they are called information. Data is thereby “transformed to communicate meaning or knowledge, ideas or conclusions” (Davis and Olsen 1985; Senn 1990, p. 35).

Today, enormous amounts of data, known as “big data,” record details of individual events and objects. The word “data refers to the information for computer processing: for example texts, numbers, sounds, images which is suitable to be processed” (Toker 2013, p. 752). In this context, data protection refers to protecting unauthorized access to available data (Toker 2015). It protects people whose personal details are held on computers against improper use or storage of that data.

The second term, Corporate Social Responsibility (CSR), refers to a voluntary business movement that encourages companies to behave responsibly regarding the impact of their activities

on different stakeholders, such as customers, employees, communities, and the environment. It is also defined as “the continuing commitment by business to behave ethically and contribute to economic development, while improving the quality of life of the workforce and their families, as well as the local community and society at large” (World Business Council for Sustainable Development 2002). The EU’s definition also emphasizes the voluntary commitment of business in CSR, as “a concept whereby companies integrate social and environmental concerns in their business operations and in their interaction with their stakeholders on a voluntary basis” (EU 2002). Since the 1960s, CSR has been frequently referred to in both business and scholarly debates.

Recent CSR Action: Protection of Data

Faced with ever-increasing global problems, such as climate change, child labor, genetically modified foods, unsustainable forestry, and ozone depletion, CSR has emerged to describe the interest of the corporate world in these global challenges. Although there is no single definition of CSR, it has been described as the voluntary interaction of businesses with social and environmental concerns in their operations to maintain their ethical image and reputation. It has expanded rapidly so that Fortune Global 500 firms are currently spending more than \$20 billion a year on their CSR initiatives (Sutherland 2018). Accordingly, the amount of CSR information provided by companies grows rapidly every year (Perez et al. 2018), with more than 80% of Fortune 500 companies including CSR reports on their websites to inform their stakeholders about their CSR commitment and promote their public image (Lii and Lee 2012). The phenomenon has appeared on the boardroom agenda and is a mainstream practice in many organizations.

Another important contribution to society is the fast-growing use and demand of technology, which has opened up businesses to public scrutiny and empowered individuals as customers and concerned citizens. Today, internet and online

tools are an everyday necessity, such that the former head of the UN’s global telecommunications regulator has claimed that governments should regard the internet as basic infrastructure – just like roads, waste, and water. Global public opinion seems to overwhelmingly agree. The natural side effect of these technological developments is that our personal lives have become digitally available to search while data is much more personal and valuable. In line with this digitalization, Fortune 100 firms have embraced privacy as part of their CSR over the last 3 years. Events and crises have become increasingly related with data protection, and mainstream discourse about the role corporations should play in advancing and addressing social and global challenges. The recent data protection violations involving Facebook and Cambridge Analytica are an important example of how data has become “the new corporate currency” of the information age. Thus, data protection is an important challenge of the twenty-first century. Large amounts of customer-related data are collected and stored for marketing and other purposes to increase business revenue (Matwyshyn 2010), so ensuring information security and finding data protection solutions is for now an essential part of business CSR actions.

A general agreement in the field is that data protection is itself a new form of CSR and therefore consumer data protection and privacy is a natural part of the agenda for the business today. After the recent Facebook scandals, more people have understood the manipulative power of technology companies over their political and everyday lives. Accordingly, one strong monitoring actor, the Global Reporting Initiative (GRI), has added a new section regarding consumer privacy under product responsibility in its G4 CSR reporting schema. Similarly, the OECD Guidelines for Multinational Enterprises (MNE) also direct MNEs to take measures to secure personal data and respect consumer privacy. Through the CSR philosophy, corporations need to accept data protection and prioritize it as much as product quality or financial sustainability. Companies like Toshiba are already following suit by including data protection as a section in their annual

CSR reports (Toshiba 2014) while also adding information regarding the company's personal data protection policy and its management standards. All Toshiba managers receive information security education through its Privacy Mark Certification. In sum, the company is approaching data protection as a core business strategy and CSR initiative rather than as just an information security issue.

Various laws and regulations also safeguard privacy and protect data, which have resulted in major information companies facing fines in Europe. In 2018, the EU introduced a new law on data protection and privacy, called the General Data Protection Regulation (GDPR). The GDPR is designed to increase citizen privacy and confidentiality, and support their right to better control their personal information, including medical records, bank statements, and Internet searches (EU GDPR 2018). This recent law has greatly affected the privacy practices of companies globally while also shaping corporate responsibility programs. The law provides a right to receive clear and understandable information about who is processing personal data, what data, and why they are processing it (EU GDPR 2018). Particularly innovative, it gives the right to request one service provider to transfer your personal data to another service provider when switching internet social networks or cloud providers. Meanwhile, it gives a person the right "to be forgotten" for the first time. Individuals can now ask companies to delete their personal data as there is no legitimate reason for keeping it. Moreover, companies will need customer consent to process personal data, for which they will have to ask the customer while clearly indicating what use will be made of such personal data.

Privacy and data protection are most often associated with compliance with the relevant legislation. However, by promoting data protection, CSR could be a powerful tool to establish a business environment that respects privacy. A company that includes privacy and consumer data protection in its CSR agenda is expected to practice the following (Makarovic 2016):

- Develop a clear, visible, and comprehensive privacy policy for all consumers and stakeholders.
- Give consumers the opportunity to opt out of supplying and clearly explain the company's uses of their personal data.
- Integrate data protection management into the company's high-level decision-making processes by appointing a Data Protection Officer before using new data processing methods such as Big Data analysis.

Summary

The world faces diverse social issues attendant with growing populations, aging societies, fast-growing demands for energy, shortages of national resources, and global environmental problems. CSR is one business response to these challenges. In the new era, data protection has become an integral part of consumer/customer issues. Planet, People, Profit, and Protection (of personal data) is becoming a new part of CSR business language. Given all the reporting required for CSR, data protection seems the next logical step. Although views differ on the exact meaning of CSR, it is generally accepted that it entails going beyond what is legally required.

Today, consumers no longer rely on government institutions to legislate to safeguard data privacy. A responsible corporate policy can allow better and more sustainable data processing, thereby furthering the potential of data to improve human existence. There is a growing view that business needs to integrate a corporate commitment to privacy within the framework of CSR, and include the issue in CSR reports. To achieve socially responsible data protection, a business can follow the following guides:

- Embed and prioritize data protection and security in company management and processes.
- Be transparent to all stakeholders about the collection and the use of their data.
- Balance profit and citizens' benefits.
- Publish relevant statistics from anonymized data to improve society.

- Allocate revenue to awareness-raising activities to counter the negative effects of a data-centric society.

Organizations face two powerful forces, given recent trends and the EU's GDPR: first, there is the growing global pressure of regulatory requirements regarding data protection; second, customers and other stakeholders are increasingly aware about their privacy rights, which will encourage them to take action in their relationships with businesses.

CSR and communication; CSR and mass media; CSR and media relations; CSR and new media; CSR and social media; CSR communication strategy; Integrated CSR communication

Definition

In today's world, relations between business, state, and society are changing. CSR and the media are the main driver, an important player and sometimes an undeniable barrier to this. Both traditional and social media are crucial for public perceptions about what CSR is, what it should be, and how business responds to outside demands. Companies depend on the media for their CSR activities, with social media, more than traditional media, becoming a bulletin board for trade and commerce in the future. The media can make CSR newsworthy within an effective communication strategy.

Introduction

The media or mass media refers to various written and visual communication vehicles, ranging from newspapers to radio, television, music, and social media. Mass media production operates on a large scale to reach everyone in a society through television images and radio shows, newspaper articles, magazine ads, social media shares, YouTube videos, and Twitter texts. The Canadian communication theoretician Marshall McLuhan described our relationship with the media as that of fish who remain unaware that they are surrounded by water. The main goal for readers and audiences who consume media is to gain information and entertainment, so the media foremost inform us, entertain us, surprise us, or lead us. In the twenty-first century, "we can easily claim that the media is a central cultural phenomenon of our society" (Luhmann 2000, p. 1) because what we know about society we learn through the mass media. As a powerful agenda setter, it creates an arena for making political, social, cultural, and economic actors visible in public; it defines our everyday lives.

Faced with ever-increasing global problems, such as climate change, child labor, genetically modified foods, unsustainable forestry, and ozone depletion, CSR has emerged to describe the interest of the corporate world in these global challenges. Although there is no single, global

definition of CSR, it has been described as a voluntary interaction: "A concept whereby companies integrate social and environmental concerns in their business operations and in their interaction with their stakeholders on a voluntary basis" (EU Commission Green Paper 2001). These changes in business decision-making, which gives central importance to "ethical values, compliance with legal requirements, and respect for people, communities and the environment" (World Business Council for Sustainable Development 2002, p. 1), are a key feature of CSR today. CSR is a socially constructed phenomenon (Turker 2018, p. 5), which has been accepted as a responsibility of enterprises regarding their impacts on society (EC 2012).

History of CSR and Media Relations

The relation of business with the media regarding CSR dates back to the 1960s with Amnesty International and the World Wildlife Fund's (WWF) efforts and Rachel Carson's book *Silent Spring* (Griswold 2012). According to Hamilton, only a few articles in the New York Times referred to CSR from 1900 through the 1960s (Hamilton 2003, p. 5). However, its use exploded after awareness-raising activities in the 1970s, with stories focusing on pollution and shareholder actions around CSR debates. Thus, this era was characterized by "wild interest" in CSR. During the 1970s, CSR became a routine concept regarding the expected costs of doing business, in an era of "mainstreaming CSR." In parallel with the growing number of social and environmental problems, business organizations have started to adopt more sustainable and socially responsible ways of doing business. Consequently, CSR and sustainable development issues have become part of the regular media agenda since the 1990s. During the late 1990s, new concepts were added, such as global social investment, corporate reputation, and corporate social policy. Furthermore, media coverage of major conferences, such as the 1992 Earth Summit, the 2002 World Economic Forum's New York event, and the World Summit on Sustainable Development in Johannesburg, all helped

to increase media coverage of CSR issues. These international conferences also set the agenda for CSR coverage. It became no longer enough for corporations to do their bit for social causes. More importantly, they had to also share it with the general audience and become an example for others to follow (Toker and Tat 2018, p. 902). Indeed, the media have a huge role to play in how CSR is published or broadcast to the world at large through their agenda-setting function. Thus, the new era has created extensive media interest in and coverage of CSR-related topics (Matten and Moon 2004, p. 324). Meanwhile, we know there is a growing CSR-related interest in business and academia in North America and Europe (Carroll 1999; Wolf 2002; Matten and Moon 2004; Küskü and Zarkada 2004; Toker et al. 2016; Turker 2018).

Variables in CSR Media Relations

Today, society's increasing awareness of social responsibility has encouraged business CSR activities. The foremost reason for increasing media coverage of CSR is the importance of the topic for society at large. The increasing awareness of society regarding global problems and companies' role and responsibility to solve them have forced companies to be more active in CSR projects and programs. According to one survey in 2002, 80% of people thought business enterprises had a moral responsibility regarding society (MORI 2003). Ten years later, the public similarly emphasized honesty, integrity, and reputation as the three fundamentals to judge a company (IPSOS MORI Reputation Center 2012). Other studies have found that consumer awareness and knowledge of CSR activities are positively connected to their purchase intentions (Lee and Shin 2010; Jablonkai 2014, p. 214). Although society's CSR-related information needs also vary from country to country, there is clearly a general information desire. Americans are ready to hear about all the CSR activities of companies as frequently as possible, while 51% of Nordic citizens prefer minimal releases on websites (Jablonkai 2014, p. 215). A careful analysis of

target stakeholders in every country clearly indicates that the public want CSR-related content, making the media an important player in CSR communication.

The importance of CSR for different stakeholders, such as consumers, employees, investors, and ordinary people, is growing. CSR has been accepted as a civic responsibility or even a taken-for-granted business behavior. The media is the most important stakeholder for developing a company's corporate visibility and reputation. A company's media visibility makes information about the company accessible to the wider society. For example, firms with the highest ranking in the Corporate Reputation Index published by Fortune are those with more visibility in the media (Toker 2013).

Beside their face-to-face communication, more and more people use the media as a way of finding out what is happening around them (Baskin et al. 1997, p. 197). The media also have a significant influence on public opinion in the context of CSR (Carroll and McCombs 2003). This influence on the salience of CSR issues and the public agenda comprise the agenda-setting role of the news media (McCombs and Reynolds 2002). Agenda-setting theory emphasizes that the prominence of elements in the news influences their salience in the public agenda (Carroll and McCombs 2003). Thus, as an important stakeholder, the media starts public discussion and affects business performance, which helps to shape corporate reputation. The media can make CSR newsworthy provided the company has an effective CSR communication strategy.

Although the media has an important place in CSR communication, CSR and media relations also face some criticisms. Due to the sensitive nature of CSR communications, CSR initiatives clearly differentiate themselves from advertising in order to avoid being perceived as a corporate image tactic and PR tool. Consumers even prefer CSR initiatives to be communicated through "silent" channels, such as annual reports and websites (Pomering and Dolnicar 2009).

Beside these criticisms of companies' CSR communication strategies, some researchers criticize the limited or negative coverage of corporate

responsibility in the media as reflecting media hostility or ignorance about business. In fact, the problem is more complicated than accusing the actors in the process. Rather, both business and the media have to work harder to find ways to explain responsible business and corporate sustainability issues that are relevant to readers.

The main accusation regarding the media's treatment of CSR issues is that they cover the topic mostly as community involvement and charitable giving by companies. Of course, there are some notable exceptions, such as the serious, broad, and distinctive focus on the topic by the *Financial Times* and *New York Times International Edition*, regarding Ethical Corporation, Corporate Citizenship Briefing, Ethical Performance, CSRWire, etc. Another criticism is that the media gives preferential treatment to companies that are already known as CSR pioneers, such as The Body Shop and Ben & Jerry's, or only focuses on the mishaps of major companies, such as Shell (marine ecology, human rights), Norsk Hydro (environmental contamination), Mitsubishi Motors (sexual harassment), Texaco (racial discrimination), Nike (child labor), ExxonMobil (climate change), or Volkswagen (environmental corruption) (Good News & Bad 2002, p. 22).

Summary

The media's key characteristic is the wide and anonymous production for the masses, which reaches nearly everyone in society. The media so fully saturate our everyday lives that we are often unconscious of their presence and their level of influence. The media is also important for the social, economic, and political actors by creating an arena to make them publically visible. In short, what we know about society and the world we learn through the mass media's lenses. Accordingly, Mark-Herbert and von Schantz (2007, p. 6) claim that the "media deserves particular attention. What is portrayed in media will influence internal as well as other external stakeholders that in their own turn may affect others. Their role can be seen as ambassadors of message and opinions."

More and more people use the media to identify changes around them. Corporations today lean on social responsibility to "enhance overall corporate image, improve relations with political stakeholders, and foster brand recognition for corporate goods and services, as well as benevolent motivations of management" (Leisinger 2007, p. 326). A number of start-ups have incorporated CSR as the engine that powers their business model. For example, TOMS is perhaps best known as the one-for-one company: for each pair of shoes it sells, it donates one pair to someone in need. The company benefited in its early days from incredible media visibility, appearing in a 2006 issue of Vogue magazine, which helped greatly expand the company's footprint and profitability (Vogue 2006, p. 248). Thus, the media are the most essential element of strategic CSR communication today.

In the new era that we are facing, consumers expect businesses to be socially responsible, and they also demand to be informed about the issue. Therefore, strategic communication is essential for company survival. Through CSR activities they can maintain their ethical image and reputation. Accordingly, the amount of CSR information provided by companies grows rapidly every year (Tench et al. 2007; Perez et al. 2018), with more than 80% of Fortune 500 companies including CSR reports on their websites to inform their stakeholders about their CSR commitment and promote their public image (Lii and Lee 2012).

Although the media are important in CSR communication, there are some doubts about CSR and media relations. Media choice and media use for CSR activities can sometimes be perceived as a corporate image tactic and PR tool, rather than reflecting a firm's values and ethical commitments. It is therefore important to highlight the effectiveness of CSR communication efforts. Due to the sensitive nature of CSR communications, CSR initiatives cannot be advertised in the same way as products or services, which creates a much more complex challenge for marketers and advertisers. The border between public relations, advertising, and the real input of corporations in social development is envisioned by media. The question seems to be how the media can contribute to

societal development and successful CSR implementation rather than how to make CSR newsworthy. A successful CSR communication strategy and media relations start with asking what the guidelines are on how to construct, maintain, and develop a genuine CSR program for different types of media companies.

In short, CSR has become an important part of business-society relations with the media as a mediator in this process. Media companies are both carriers and barriers regarding the CSR and social development agendas. Research into news articles is needed to understand the relationship between business and media.

CSR and Role of Government as a Regulator

Andrea Venturelli and Simone Pizzi
Department of Economic Sciences, Università del Salento, Lecce, Italy

Synonyms

Institution

Definition

The government plays a central role in corporate social responsibility (CSR) as a regulator.

Although many academics define CSR as a voluntary approach, an increasing number of governments have introduced regulation making it mandatory.

In recent years, governments have started to discuss the implementation of common rules at the international level. A typical case study is represented by Directive 95/2014/EC about non-financial reporting, which represents a first attempt to harmonize non-financial reporting in Europe. Furthermore, governments play a central role even at the global level. Specifically, all worldwide governments have subscribed the 2030 Agenda, and their contribution has not been limited to subscription but includes steps for control in the private sector.

These new forms of regulation have covered different topics like nonfinancial reporting, control of GHG emissions and rewards for ethical business practices. However, the “real” role played by governments in corporate social responsibility is the subject of several differing opinions among academics. Some have shown how CSR practices connected to legal provisions are conducted as part of a bureaucratic approach to be compliant with the law, and not from an effective cultural change by businesses’ managers.

The Role of Governments in CSR

Recently, governments have deeply analyzed the opportunity to identify new policies and laws about CSR. In response, different governments have taken different approaches. Specifically, academics have been distinguished between “soft” and “hard” forms of regulation around CSR (Gjølberg 2011; Steurer et al. 2012).

The main differences between hard and soft forms of regulation are their different impacts on firms (Yan 2019). Specifically, “soft” regulation for CSR consists of a government’s provision of rules that encourage companies to be more ethical and sustainable. On the other hand, “hard” regulation consists of a set of mandatory provisions to reduce irresponsible behaviors. Moreover, nowadays it is possible to identify a new

form of hybrid regulation for CSR (Steurer et al. 2012). An example of this hybrid form of regulation is Directive 95/2014/EC. The “hard” side of the Directive is the mandatory provision for PIEs to disclose nonfinancial information, while the “soft” side is the opportunity for SMEs to prepare reports in accordance with the Directive (Venturelli et al. 2019).

The content of the Directive is innovative because many of the Member States did not yet have specific forms of regulation about CSR (Steurer et al. 2012). Since 2016, European governments have transposed the content of the Directive into their national legal systems. According to the “gold ban” principle, the transposition of the Directive by Member States has involved different degrees of adherence to the original contents (CSR Europe and Global Reporting Initiative 2017). Specifically, the transposition of the rule has led to changes about the mandatory provision of third-party independent assurance, the form and the substance of the information provided.

The Debate About CSR Regulation

Regulation in corporate social responsibility (CSR) has been widely analyzed by academics. It is a relevant yet complex issue because of the difficulty of assigning a set of mandatory rules to a voluntary behavior. Furthermore, conceptualizing corporate social responsibility has been made more difficult by the absence of a common definition. In recent years, academics and policymakers have provided several definitions of CSR.

At the academic level, some authors have tried to identify a widely adopted definition of CSR. The studies conducted by Dalshrud (2008) reported the existence of 37 definitions of CSR at the time of the study. The authors identified the most common definition of CSR through a word count meta-analysis. This analysis revealed many of the definitions consisted of activities not related to external pressure from governments. In particular, in some definitions the concept of “voluntary” is explicit.

At the policy level, the first definition of corporate social responsibility was provided by the European Commission (2011) who defined it as “the responsibility of enterprises for their impact on society” and noted that “therefore, it should be company led.” Furthermore, the European Commission assigns a supporting role to governments for the effective introduction of corporate social responsibility paradigms within enterprises. However, the European Commission suggests the provision of voluntary policies foremost, and only residually the introduction of mandatory provisions.

According to this evidence, governments play a central role in terms of regulation. However, the concept of CSR requires a direct contribution from companies through their personal beliefs about sustainability and ethics.

Summary

Sustainable development represents a new challenge for worldwide policymakers. Although CSR is considered as a “voluntary behavior” by academics, recently an increasing number of laws about this topic have been introduced. Furthermore, the political activity about CSR has been encouraged by the cooperation between Member States to establish a set of common rules about nonfinancial reporting. Moreover, in the 2030 Agenda, the UN has introduced an explicit provision about the role of governments to support the SDGs’ achievement through new forms of regulation.

CSR and Soccer

Nicole Konnowski
Hochschule Fresenius, Hamburg, Germany

Introduction

There is no clear definition of the term Corporate Social Responsibility (CSR), because it is used very inconsistently. According to ISO 26000, CSR generally means the “responsibility of an organization for the impact of its decisions and activities on society and the environment.” This definition applies to professional soccer clubs as well. The goal is the integration of social and ecological consciousness in decision-making processes.

There has been an increasing importance in assuming corporate social responsibility in sports and soccer management over the past 10 years. This article refers primarily to the German soccer market. It is striking that CSR is an interdisciplinary topic. It is studied by sports science, economics, and technological studies (Walzel 2019).

Soccer as a Commodity

No other sport inspires people around the world as much as soccer. Professional soccer clubs, originally oriented towards recreational and social interaction (the common good), became commercial enterprises (see ► “CSR and Sports”). Especially in recent years, professional soccer has recorded steady growth and climbing sales profits. Player wages are rising, transfer fees are reaching record highs, and media generated revenue is rising steadily. Soccer has become a major economic factor. As a result, the professional clubs are structured like modern business enterprises. Professional soccer is subject to continuous economization, commercialization, medialization, and professionalization. In addition to delivering athletic performance, the professional clubs must prove themselves financially. Most clubs have broken off their pro divisions into corporate entities.

In contrast to the negative effects of commercialization such as corruption, match-manipulation, and violence, soccer can also positively influence society because of its media coverage and public attention. Soccer reflects society, positively and negatively. The professional soccer clubs are oriented towards big enterprise and like many other businesses, the soccer clubs are aware of this responsibility and have integrated CSR measures (Walzel 2019). Nevertheless, soccer differs significantly from other economic goods and therefore the CSR measures differ as well (Walzel 2019) (see ► “CSR and Sports”).

According to Daumann (2015), the athletic performance of the soccer players and clubs is sold to the spectator. Of particular importance to

the entertainment value is the uncertain outcome of a game. This provides excitement and captivates the viewer. While the consumer expects reliability and transparency in other products, “sports performance” as a commodity thrives on the emotions of the fans. Another unique quality is the great public attention that soccer generates. Both positive and negative news about soccer are dominating the headlines. No other industry has such coverage. Professional sports have a very heterogeneous target group, which makes the product difficult to promote. The interests of the spectators vary.

Incentives

There are many reasons for professional soccer clubs to integrate CSR measures. One reason is the public attention that soccer draws to it. Another reason is the normative expectation of society. The professional soccer club used to be a part of the local community. Due to the commercialization, the professional soccer club has partly moved away from local interests. The hometown identification with the club and the players is decreasing. CSR measures can strengthen the relationship with the local community. Furthermore, CSR measures can be understood in response to societal changes and challenges. The coverage and media attention can be used to sensitize the audience to social problems. The clubs should serve as role models here. Ideally, CSR measures should be cost effective or even generate extra revenue. This could result in improved fan loyalty and gaining like-minded sponsors. There is also increasing social pressure. The stakeholders (fans, media, and sponsors) demand social commitment. Given the profits and privileged status of clubs, many take it for granted that clubs are socially engaged. If a club does not get involved, this could lead to image deterioration, a declining fan base, and negative publicity. Another reason to implement CSR practices is that other clubs already model this successfully. In addition, government can

support sports through appropriate regulations and policies. So far this has only been the case in Germany for the Green Goal Football World Cup 2006 and 2011 women’s campaign (Walzel 2019).

Areas of Action for CSR Measures

Many trends in the classic economy are imitated by professional soccer organizations – it is the same with CSR strategies. The first clubs started donating money to charity. Then they started to implement classic CSR measures. These involved in particular the areas of energy, water, emissions, and waste. For example, attempts were made to produce less waste, to save energy and water, and to minimize discharge of emissions (Weber 2019).

The areas of action in which professional soccer clubs engage are so diverse and vary by country. From country to country different priorities are set according to the social situation and degree of sports development. In general, the commitment is to social and environmental responsibility. Areas of involvement include health and education, fan outreach, sports and movement, children and adolescents, family, former players, violence and drugs, ethics, racism, and the environment. The variety of CSR measures makes comparability and control of the measures difficult.

Implementation and Impact of CSR Measures

The implementation of CSR measures takes place in different ways: for example, some soccer clubs or federations, like the German Football League (DFL), establish foundations, others have their own CSR department or staff units (Werheid and Mühlen 2019). CSR action includes local, regional, national, and international measures.

Successfully implemented CSR measures can bring pride and a higher level of identification of the fans with their club. CSR management can contribute to an image improvement of the

professional soccer club or sports federation. Well-executed CSR measures ideally lead to a perfect win-win situation for society and the sports organization (Ermes and Luthe 2019). To reach this outcome, it is important that the chosen CSR strategy fits the respective club. They should be perceived as selfless (Kulczycki and Königstorfer 2016). In this way, the cohesion of a society can be strengthened, the identification with a region or a country can be intensified, and further positive effects can be achieved. Athletic success cannot fully be planned but with well-implemented CSR measures, the soccer clubs' popularity can become independent of sporting success.

Ermes and Luthe (2019) have developed the following guidelines for individual and authentic CSR management:

- What does sustainability mean for my club?
- Why take responsibility?
- What goals do we want to achieve with the assumption of responsibility?
- What are the values of my club?
- Which stakeholder groups are there and what are their expectations of the soccer organization?
- Which stakeholder groups are particularly relevant for the soccer club, have a special influence or interest?

From these individual guidelines, CSR management can be developed. The interests of all stakeholders must be taken into consideration. The professional soccer clubs make a contribution to social responsibility. They must be able to strike a balance between corporate economic goals and social as well as environmental interests. Soccer sportsmanship stands for values such as solidarity, tolerance, and fairness. On one hand, this can be used for a positive image. On the other hand, the risk is greater: scandals spread faster due to public attention. This can lead to a negative club image. (Ermes and Luthe 2019).

To sum it up, research on the long-term effect of CSR in soccer is in its beginning stages and

more data is needed to issue conclusive statements.

Case Study: Soccer Club "Fußball-Club St. Pauli von 1910 e.V."

The implementation of CSR measures is just as varied as the areas of actions. Thus, the DFL has established a foundation, some clubs found junior sports academies, which support the educational and personal development of the young soccer players in addition to physical education.

In the following, CSR measures of the Fußball-Club St Pauli von 1910 e.V., commonly known as FC St Pauli, will be presented. FC St. Pauli is a German multi-division club, whose largest division is the soccer department. FC St. Pauli is currently playing in the 2nd Bundesliga. Unlike other professional clubs, St. Pauli has not outsourced its professional players to a corporation. The reasons are not only economical but also reflect social and philosophical values. FC St. Pauli is known for cultivating a very close relationship with its fans and supporters by taking a political position and addressing social challenges in their community (FC St. Pauli 2001).

The soccer club presents itself as down to earth and, despite commercialization, it conveys values that embody the sport such as tolerance and respect. In addition to athletic success, FC St. Pauli embodies a particular lifestyle. As a result, the club gains attractiveness media coverage and increases its network.

Despite increasing commercialization, FC St. Pauli is building a bridge between the club and its fans (Ermes and Luthe 2019). The identification of the fans with the club is thus independent of the team's athletic success.

As early as 2009, FC St. Pauli developed guiding principles that were approved by the club's president as binding from then on. Since then, these principles have been providing the foundation for contracts, agreements, etc., and serve as guidelines for members, employees, fans, and

volunteers. For example, FC St. Pauli selects sponsors and business partners who share the club's social and political values (FC St. Pauli 2009). In addition to economic aspects, the sale of merchandise and services at FC St. Pauli is characterized by the principles of social compatibility, variety of offers, sustainability, and ecology. The FC St. Pauli also has a CSR department involved in integrating these measures. As a local soccer club, FC St. Pauli is mainly involved regionally in issues such as social integration of refugees, neighborhood, and school projects. Even transregional initiatives such as "Refugees Welcome" are part of their CSR measures (FC St. Pauli 2019).

Because of all these described activities, FC St. Pauli is a great example for implementing CSR measures successfully.

Summary

CSR in the soccer industry is a relatively new and interdisciplinary field of research as it is discussed in different sciences. Due to its unique nature, soccer cannot be compared to other industries. Both, the areas of action in which the professional clubs engage in as well as their CSR measures have a broad spectrum. Successful CSR management can strengthen fan loyalty by promoting a positive image that is independent of athletic success. A prerequisite is the individually tailored and authentic CSR management. Soccer is highly suitable for incorporating CSR management because of its popularity, high media coverage, and public attention. In order to demonstrate the effects of CSR in soccer, long-term studies are needed.

Synonyms

Corporate sustainability; CSR and soccer; Cultural understanding; Sports and its social significance; Sports and values; Sustainability awareness

Definition/Description

Sports has a great significance in society. Therefore, it offers a perfect platform for CSR measures. The goal of CSR measures in sports is to overcome the dualism between ethics and economization. The areas of action cover personnel management, environmental management, value-added chain, corporate citizenship, and communication. Because of the existing diversity of sports, the CSR concept has to be adapted individually. One important requirement for successful implementation of CSR measures is that CSR is consistently anchored in the company's mission statement and implemented in the long term.

Introduction

For about 10 years, research has been dealing with Corporate Social Responsibility (CSR) in sports. This entry primarily refers to recreational sports, while the entry ► [“CSR and Soccer”](#) focuses on professional soccer clubs.

First of all, the term “sports” and its significance in society are explained. Subsequently, the areas of action of CSR measures will be presented and recommendations for a successful implementation of CSR measures will be given. Finally, the case study of sports clubs in Germany illustrates the possibilities of sports to engage in CSR.

Sports and Its Significance in Society

The term “sports” is used worldwide; however, a uniform definition is difficult. R  thig and Prohl (2003) summarize the problem as follows:

Since the beginning of the 20th century, sports has become a colloquial term used throughout the world. A precise or even clear conceptual definition can therefore not be made. What is generally meant by sports is less a question of scientific dimensional analysis, but it is much more determined by everyday use as well as by the historical and traditional involvement in social, economic, political and legal applications. In addition, the status quo of sportsmanship changes, expands and differentiates the concept of sports itself. (p. 493)

Sports has been anchored in our society since its earliest history. Already in ancient times spectators visited the Olympic Games (as early as 776 B.C.). Our sports as we know it today has its origins in England. In the eighteenth and nineteenth centuries, physical exercises and games were structured and organized. Regulations were established.

Today, sports is exercised all over the world and permeates all areas of society. There is a social significance, bringing together people of different backgrounds and social strata. Sports also teaches values such as respect, tolerance, and fair play. Children and adolescents learn to pursue a common goal and to accept rules. Participating in sports contributes to a sense of belonging and personality development. Another important aspect is the effect on physical and emotional well-being. Exercising sports increases physical and mental performance and contributes to maintaining good health. Furthermore, many athletes pursue aesthetic sports like body-building that aim for aesthetic as well as athletic expression. Expressive sports such as dance or figure skating emphasize the aesthetic and artistic expression of sports. For politics, sports is a way of connecting people, overcoming cultural differences and geographic borders. After all, sports is also an economic factor. The athletes need sports' facilities, sports equipment, and training opportunities. In professional sports, billions of Euros are earned. In 2017, for example, soccer player Neymar da Silva Santos J  nior transferred from

Barcelona to Paris Saint-Germain in a move worth €222 million, making him the most expensive player ever.

Sports as a Commodity

“Sports” differs significantly from other economic goods. Daumann (2015) describes a dual structure of the sports market. Thus, a distinction is made between the sports market and the entertainment market. The sports market describes the market consisting of supplier, products, and consumer for the athlete. The entertainment market sells the sports-generated performance of athletes or athletic teams to the interested audience. Suppliers are represented by the organizers of sports events and by the media. The two markets are very interdependent. On the one hand, the sports media industry cannot exist without the athletic performance. On the other hand, the sports market benefits from the sales profits of the entertainment market. In addition, follow-up markets are created. These include the media rights market, advertising rights market, sponsorship, and branding rights market.

A major factor in entertainment marketing is the emotional one: No other commodity causes so much enthusiasm. The loyal spectator will follow the games of his favorite team or athlete independent of their performance.

Since sports is a very special industry, CSR should focus on the unique features of sport’s social responsibility. Smith and Westerbeek (2007) have highlighted the characteristics for CSR and sports:

1. Mass media distribution and communication power

Due to mass media, sports offers a platform to reach a broad mass of people. This bears chances and risks at the same: News and scandals are spread almost simultaneously because of the public attention.

2. Youth Appeal

Sports has an inherent appeal to young people from both a participative and spectator viewpoint. Participation-based programs can

encourage young people to involve in CSR and sustainability measures, and elite athletes could serve as role models for emulation, especially in the field of CSR.

3. Positive health impacts

Exercising sports can help to keep in shape and stay healthy. Sports has innumerable physical health benefits such as improved cardiorespiratory and muscular fitness, coronary health, and cancer prevention.

4. Social interaction

Sports offers an ideal platform for encouraging social interaction. Probably overstated and with notable exceptions like aggression and violence, participating in sports can be a force for stability, democracy, and peace.

5. Sustainability awareness

Sports and sporting events can increase people’s awareness of environment and of sustainability. Programs promoting sustainability like the Olympic Games 2012 in London have the opportunity to reduce the environmental impact.

6. Cultural understanding and integration

Sporting events like the Olympic Games were established to connect young people of different cultures in a peaceful way. Sports promotes a shared sense of belonging and participation and may therefore also be an important tool for the integration of immigrants.

7. Immediate gratification benefits

Participating in sports can be fun and satisfying.

Due to the described characteristics and the thematic proximity, the sports industry is very suitable to integrate and implement CSR measures. The ideals of sports already reflect social responsibility. Sports has great potential to influence positive changes in society. The sports industry is also a communicator and enhancer of values and ideas to a broad range of people and especially to young people (Kolb 2014).

Therefore, CSR is becoming increasingly important in sports and sports organizations. In addition, traditional businesses use sports as a platform to implement their own sustainability measures.

Areas of Action of CSR and Sports

Many sports organizations have engaged in philanthropy, community involvement, health education, and issues such as inclusion and antidiscrimination. CSR and sports follows general CSR areas of action. These cover.

1. Personnel management
 - Recruiting
 - Personnel appraisal
 - Human resource development
2. Environmental management
 - Water management
 - Energy management
 - Waste management
 - Mobility management
 - Catering
3. Value-added chain
 - Do not enter into business relationships that violate human rights
 - Maintaining fundamental and human rights through fan culture
4. Corporate citizenship
 - Use synergy effects with other companies or organizations
5. Communication
 - By mission statement
 - Employees' identification with the chosen CSR strategy (Keller 2014)

Requirements of Successful CSR Implementation

Apart from clear goals and analysis of the outcomes, following requirements for a successful implementation of CSR measures are necessary:

- Linking the CSR strategy with the overall strategy of the sports organization
- Selection of CSR activities that fit the brand of sports organizations to ensure credibility and sustainability
- Communication of CSR activities through impactful branding in compliance with current trademark brokerage guidelines (differentiation, recognition, identification)

- Check for availability of the required structural, human, and financial resources
- Targeted use of sports organization-specific core competencies, such as training know-how, location, and media networking
- Involvement of partners, from nonprofit organizations, government agencies, and/or commercial enterprises, to the use of financial, structural, and personnel assets
- Involvement of officials and athletes as testimonials as role models
- Transparent documentation of CSR activities
- Constant willingness to learn and to optimize the chosen CSR strategy (Keller 2014)

Case Study: Sports Clubs in Germany

The structure of sports clubs in Germany is a special one that already includes some CSR aspects from the ground up. According to Fahrner (2012), "sports clubs are permanent associations of persons to pursue a common purpose." They are characterized by

- A central organizational basis
- Voluntary association in the legal form of the registered sports club
- Nonprofit sports club as prevailing legal form
- Association as a "legal entity" – members are not personally liable, liability is limited to club assets

In recreational sports, the nonprofit and charitable registered club outweighs. To qualify as a nonprofit, specific conditions must be met:

- Selfless promotion of the general public in the material, spiritual, or moral field of action
- Not for profit
- Nonexclusive, must be accessible for everyone
- Not limited to professional sports (combination of professional and amateur sports is possible)
- Funds available for statutory purposes only
- No profit sharing for club members
- No disproportionate or unrelated expenses
- Timely use of funds

The nonprofit sports club is checked by the tax office every 3 years (Fahrner 2012).

Advantages of a nonprofit sports club are tax benefits and exclusion of personal liability. Sports clubs should be accessible to everyone, so there are often special rates that allow disadvantaged people and families to participate in sports and thus in social life as well. According to a recent survey, the goals of sports clubs showed that above all the conveyance of values, the affordable training offers, the integration, and inclusion play an important role and joint activities are valued. Volunteering is also considered a high priority (statista 2019).

Since sports clubs offer an important social environment, they are often subsidized by local government. In addition to tax benefits, the sports clubs are partially funded financially. Potential profits are reinvested in the sports clubs or federation in alignment with the association's guideline. The sports clubs are primarily focused on member interests and needs. Decisions are made democratically by the members at a general meeting (Fahrner 2012).

Sports clubs shape our society and create social cohesion. Sports culture collectively mirrors societal values and tensions; therefore, both positive and negative behaviors are observed. Racism and discrimination unfortunately also occur in sports. Sports clubs have to adapt to the diversity of society (Lüders 2014). In addition, sports clubs are increasingly confronted with the rising expectations of their members. The willingness to volunteer decreases and the demographic change results in fewer members. Sports clubs have to deal with the commercialization of recreational sports. CSR offers a way to break away from the profit-oriented providers.

Due to the diversity of sports clubs, no clear CSR strategy can be recommended for all sports clubs. The sports clubs have their responsibilities and the areas of activity. They might also need the support of sports federations. Implementation of CSR could be realized by athletes acting as a role model, sports organizations, specific campaigns, and outsourced institutions like foundations (Trosien 2014).

Summary

Due to the diversity in sports, there is no CSR concept that fits all varieties of sports. It has to be adapted individually. The goal of CSR measures in sports is to overcome the dualism between ethics and economization. Ideally, a win-win situation is created for the companies as well as society. Businesses must therefore themselves be considered part of society and identify areas of conflict with the environment and communicate these issues with the stakeholders.

One important requirement is that CSR is consistently anchored in the company's mission statement and implemented in the long term.

In times of increasing commercial competition, sports clubs have the chance represent values by implementing CSR measures and increase the attractiveness for members this way.

- management styles, and relations with stakeholders to many activities. With the increasing competition and increasing environmental and social awareness, the expectation of the society is changing. The perspective that every product and service produced in the past creates a high economic value has now left its place to the understanding of how the products and services produced can benefit society. The fact that companies consider the benefit of society while carrying out their activities not only provides a competitive advantage, but also offers an important advantage in terms of the message it gives to all its stakeholders. Carroll (1979, 1991) considers social responsibility in four dimensions as economic, legal, ethical, and philanthropic responsibilities, and these responsibilities express the expectations imposed on the company as a whole by the company's stakeholders and society. It is possible to define the social responsibility activities carried out by the companies as the activities carried out to improve and increase the welfare level of the society.

CSR Concept

The concept of social responsibility, which is included in H. Bowen's book *Social Responsibilities of Businessmen*, which was first published in 1953, is encountered with many different definitions in literature today. Bowen (1953) argues that businessmen should engage in social responsibility activities that coincide with the values and goals of society. The European Commission defines corporate social responsibility as the ability of companies to integrate social and environmental issues into their activities on a voluntary basis (European Commission, 2001).

Scholars from different disciplines seek to establish a consensus definition of the concept of social responsibility since the post-World War II (Carroll, 1991; Carroll & Shabana, 2010). Although economic interests seem to be the primary concerns of businesses, the perspective has expanded by the recognition of the idea that a business has social and environmental

responsibilities besides the economic interests and legal obligations (Carroll, 1979, p.497; Carroll & Shabana, 2010). CSR pyramid proposed by Carroll (1979, 1991) indicates that the business is required to fulfill its economic, legal, ethical, and discretionary (philanthropic) responsibilities simultaneously, so that a company has several responsibilities including “make a profit, obey the law, be ethical and be a good corporate citizen” (Carroll, 1991, p.39–42). Based on this, CSR refers to responsible behaviors and practices to company’s stakeholders, thinking and going beyond satisfying only shareholders’ interests and making efforts to develop balanced relations with all stakeholders of a company (Fernández-Guadano & Sarria-Pedroza, 2018). Within this context, it is considered that the CSR has significantly evolved from profit maximization for shareholders to value creation for the society (Branco & Rodrigues, 2007, p.5). Thus, CSR is considered as a value driver that leads to value creation for primary stakeholders. In this vein, the context of CSR has developed from philanthropy to value creation and afterward to the concept of shared value (Bosch-Badia et al., 2013, pp.12–13).

With the concept of social responsibility gaining importance for both academic circles and the business world, corporate social responsibility activities have become one of the important strategies that companies apply to raise awareness. It is basically a concept that brings together public, private, and nongovernmental organizations and directs them to work together for a purpose. Companies interacting with their environment must behave in line with the expectations of the society and act with a sense of responsibility while carrying out their activities. Beyond being a company that only produces goods and services, it is expected to display behaviors that consider its employees, protect the environment, and care about consumer rights. With this point of view, the fact that companies care about the interests of the society besides their own interests and deal with social problems will ensure that they reflect their social responsibility awareness to the society they belong to.

General Perspective of CSR and Women

CSR is considered a valuable instrument to promote gender equality in organizations so that equality and diversity seem to be the fundamental aspects of CSR. Recently, a growing number of companies are focusing on gender equality and launching CSR programs, toward empowering women both within the community and particularly in the workplace through increasing the participation of both the number and the role of women among the workforce in professional life and mitigating the problem of glass ceiling. With this purpose, CSR plays a significant and dynamic role that fosters gender equality (Sridevi, 2015).

Gender Differences

One of the research topics investigated within the scope of CSR, which has been debated from a wide range of disciplines in management literature, is the relationship between gender differences and CSR, or, in other words, the impact of gender differences on CSR practices. The empirical researches (i.e., Atakan et al., 2008; Luthar et al., 1997) reveal that gender is correlated to perceptions and evaluations of ethical behavior and ethical climate that female correspondents present more favorable ethical attitudes than males. Another research by Smith et al. (2001) indicate that women present more emphasis and attention to the extent to which a company fulfills its social and environmental responsibilities than do males. In the same vein, Marz et al. (2003) state that women significantly give more importance to social responsibilities of the companies than males.

In the context of gender, one of the indirect causes of the problems that the female gender faces in the society is the male-dominated perspective and its reflection on the behaviors. However, today’s society, which is developing day by day and its awareness is increasing, is reacting to this distinction. It arises from social, cultural, and economic phenomena on the basis of differences other than the biological differences that exist between men and women.

As customers, employees, suppliers, and members of society from a broad perspective, women

are stakeholders of companies. Gender equality, which is an important issue of corporate social responsibility, has to maintain its priority among the issues handled by companies (Grosser & Moon, 2005).

It is a known fact that women and men differ in their values from past to present, and this difference also shows itself when it comes to social responsibility. Many studies show that women are more concerned with environmental problems than men (Diamantopoulos et al., 2003), they are more concerned about environmental risks (Bord & O'Connor, 1997; Davidson & Freudenburg, 1996) and reveal that they take care to consume environmentally friendly products in their consumption habits (Mainieri et al., 1997). They claim that the most important reasons for this situation arise either from their biological characteristics, because they closely resemble nature with the effect of their reproductive roles, or that they are more aware of the exploitation on the environment with the effect of the paternalist structure in the society (Wehrmeyer & McNeil, 2000).

Women on Boards

Board of directors, which is an important part of the corporate governance system of companies (Vigano et al., 2011), is a mechanism that determines corporate social responsibility activities, which is a strategic activity (Arora & Dharwadkar, 2011; Dehaene et al., 2001). It is known that the decisions taken by the boards of directors have a significant impact on activities that fall within the scope of social responsibility such as health, environment, security, and philanthropy (Huse et al., 2009); from this perspective, the diversity of the boards will facilitate the determination of the needs of different stakeholder groups, especially with the increase in the number of women in the board. It is suggested that the decisions to be taken will have an impact on the determination and reshaping of social responsibility practices (Harjoto et al., 2015).

In the literature, it is stated that the higher the gender diversity in the boards of directors, the higher the level of corporate social responsibility

activities and the social mission of the company (Siciliano, 1996; Wang & Coffey, 1992; Williams, 2003). As a result of women's social and social aspects outweighing men, it is seen that they exhibit behaviors such as empathy at both individual and organizational level, caring about the problems at all levels of the society, protecting the values that are important for the society, and they tend to determine their corporate social responsibility strategy in this direction (Burgess & Tharenou, 2002; Ibrahim & Angelidis, 1994). It can be said that the sensitive behavior of women members toward the society due to the different perspectives they display in the boards has a stronger effect on corporate social responsibility issues (Burgess & Tharenou, 2002).

Women's Empowerment

Literature reveals that there is a bidirectional relationship between economic development and women's empowerment which refers to "*improving the ability of women to access the constituents of development—in particular health, education, earning opportunities, rights, and political participation*" (Duflo, 2012, p. 1053) so that the concept has gained particular attention by scholars. It is considered that women empowerment can be provided through CSR activities (Sarkar & Singh, 2016). Particular emphasis indicates that empowered women enable significant and positive changes such as children's education and their conditions, health and nutrition, gendering development, and finally this process catalyzes human development (Abraham, 2013). Additionally, it is proved that generating and increasing employment among women in the community and increasing their income contribute to international and sustainable development. According to the data provided by International Center for Research on Women (ICRW), empowering women promotes a high return on investment so that an increasing number of companies, in particular, Coca-Cola, Vodafone, Walmart, H&M, General Mills, and many others, have totally invested more than \$300 million and initiated several CSR projects and programs to support women's economic empowerment (ICRW, 2016).

CSR Butterfly Effect

Giorgia Nigri

Department of Economics, LUMSA, Rome, Italy

Synonyms

Collective consciousness; Dependent co-arising; Oneness; Quantum theory

Definition

The butterfly effect used in chaos theory – a branch of mathematics focusing on the behavior of dynamical systems that are highly sensitive to initial conditions – describes how a small change in the initial state of a physical system can result in significant differences in a later state. The example posed by Edward Lorenz in his work, where the exact time of formation and path taken by a tornado can be influenced by minor perturbations such as the flapping of the wings of a distant butterfly several weeks earlier, diffused the term worldwide. In the field of corporate social responsibility (CSR), the CSR butterfly effect underlines how a slight change in initial social and environmental conditions can lead to widespread positive consequences. Corporate social initiatives include

philanthropy, volunteering, socially responsible business practices, cause promotions and activism, cause-related marketing, and social marketing as forms of corporate citizenship. Although research has focused on the fact that a flap of wings can be instrumental in generating a tornado, Lorenz also pointed out that it can be equally helpful in preventing a tornado, which is what CSR aims to do.

Introduction

Corporate social responsibility (CSR), defined in the Cambridge Dictionary as a company's sense of responsibility towards the community and environment in which it operates ([Cambridge Dictionary](#)), goes beyond compliance with regulatory requirements and that which is required by law and engages in actions that further social good, beyond the interests of the firm (McWilliams and Siegel 2001).

Corporate social initiatives include philanthropy, volunteering, socially responsible business practices, cause promotions and activism, cause-related marketing, and social marketing, as forms of corporate citizenship (Lee and Kotler 2013).

In the field of corporate social responsibility, the CSR butterfly effect underlines how a slight change in initial social and environmental conditions can lead to widespread positive consequences (Idowu et al. 2015).

The Butterfly Effect

The butterfly effect used in chaos theory – a branch of mathematics focusing on the behavior of dynamical systems that are highly sensitive to initial conditions – describes how a small change in the initial state of a physical system can result in significant differences in a later state (Kellert 1993; Boeing 2016).

The example posed by Edward Lorenz (1963) in his work, where the exact time of formation and path taken by a tornado can be influenced by

minor perturbations such as the flapping of the wings of a distant butterfly several weeks earlier, diffused the term worldwide.

Chaos theory, biology, and bioeconomy are all strictly correlated to economics. Although the themes of sustainability and the depletion of resources are already strongly present in economic thought with Adam Smith and Malthus, they find in Georgescu-Roegen, who cites the second theory of thermodynamics (Carnot 1979) – according to which at the end of each process the possibility that energy can still be used by someone else is always worse than at the beginning – their highest expression. Material degrades, and raw materials can be reused in the economic cycle only to a lesser extent and at the price of high energy expenditure. Matter and energy, therefore, enter the industrial process with a relatively low degree of entropy and come out with a higher entropy since spontaneous change for an irreversible process in an isolated system – one that does not exchange heat or work with its surroundings – always proceeds in the direction of increasing entropy (Drake 2018). Being two parts of an isolated system, the melting of ice in the arctic circle due to the ozone layer, for example, cannot be reversed – total entropy increases as the ice melts (Drake 2018).

From this derives the need to radically rethink economic science, making it capable of incorporating the principle of entropy and, in general, ecological constraints since a minimal change in initial conditions creates a significantly different outcome. Although research has focused on the fact that a flap of wings can be instrumental in generating a tornado, Lorenz also pointed out that the flap of a butterfly's wings can be equally instrumental in preventing a tornado (Lorenz 1963).

Corporate Social Responsibility

Moral obligations are deeply rooted in social relations and, as such, are an integral part of society. They are independent of the law and go beyond political boundaries (Castellani 2015). Social

responsibility is based primarily on the existence of moral constraints and identifies work not only as an economic or social factor but as a human factor, and as such it poses as an integral part of companies and their surrounding community (Regni 2006).

Moral obligations have always been inherent in society. However, the term social responsibility, together with the set of rules that define the moral duties of companies (economic, ethical, and environmental), entered the corporate world in 1930. The concept was introduced by Berle and Means, who identified the separation of power between management and property through the fulfillment and division of tasks, such as economic objectives on the one hand and legal obligations on the other. Their studies derived two key concepts of corporate social responsibility, stakeholder theory and stakeholder value, defined later by the work of Freeman (2010). In the 1980s, for the first time, sustainability was linked to society in the Brundtland Report (UN 1987), addressed to companies. The report focused on the aspects related to the healthiness of the workplace and the psychophysical well-being of employees in addition to the eco-sustainability of industrial production which was meant to safeguard the planet as a moral obligation towards future generations.

Over the course of time, the concept has been highly debated upon by different academic fields, and, due to the frenetic industrial expansion and globalization, it has passed from being considered a revolutionary and utopian theory to a decisive factor needed to address the ever-growing scarcity of resources (McWilliams and Siegel 2001; Aguilera et al. 2006; Lee and Kotler 2013). This brought to an increase in knowledge and attention by both investors and the public and to the need to reduce the increasingly widespread information asymmetry between the company and its stakeholders. A voluntary ancillary reporting method was introduced where the organization could describe its activities to its community of reference, the social or sustainability report – a report in which companies highlight the social impact of their activities and explain their remuneration policy and the commitments undertaken internally

(with employees) and externally (with the social context of reference) (Bebbington et al. 2009; Thijssens et al. 2016).

In South Africa the King Report published in 2010 favors the figure of corporate citizenship; the company in fact, like the citizen, has not only rights but also legal and moral obligations towards the environment in which it operates, and as a responsible operator it must protect, enhance, and invest in the environment itself to maintain these rights. From this point of view, the management action should be oriented to the achievement of objectives that create value for the company in the long term (Castellani 2015).

The idea of social responsibility is addressed not only to individuals, groups, and the community but also to private institutions and public bodies since they all share the same sphere of activity and produce effects that are potentially beneficial or harmful to all stakeholders. If companies can work globally and transnationally when it comes to profit, they can likewise assume globally ethical behavior. A company engaged in activities outside national borders should propose itself abroad with the same care and diligence that it employs in making economic choices in the community to which it belongs.

The Butterfly Effect Under the Corporate Social Responsibility Lens

Every action and non-action have an impact on the surrounding community, but for both managers and board members, the lasting effect is often hard to see because they tend to be focused on the present, in their term of service. The lack of short-term recognition and the fear of negative evaluations tend to outweigh the advantages of positive results which often tend to come at a much later time when the cause or the effects are muted or forgotten.

Hong and Sun (2000) cite butterfly effects as critical events to the normalization of diplomatic relations. In the 1970s relations between China and the USA had worsened during the Cold War. But thanks to an American player accidentally boarding the Chinese ping pong team's bus during

an international competition in Japan, friendly interactions began, resulting in the reconciliation between the countries (Strother 2016).

Mostly though, the butterfly effect is associated with a negative connotation. Two examples of adverse financial butterfly effects are the repeal of the Glass-Steagall Act – legislation that prevented commercial banks from merging with investment banks – by President Clinton in 1999, which brought to a spate of bankruptcies, including ENRON, and to the introduction of toxic financial instruments, such as CDOs (collateralized debt obligations) and CDSs (credit default swaps) into the market. The second example is when Alan Greenspan cut interest rates from 6% to 1% between 2000 and 2003 introducing NINJA – No Income, No Job, No Assets – mortgage loans, which brought to a global financial crisis (Visser 2010).

On a broader scope, the current economic paradigm has led to the enrichment of the top 1% of the population at the expense of the 99%; the rise in drug abuse and suicide rates; the non-acceptance of refugees; desertification; and, in general, the destruction of the natural environment (Laszlo 2019). Thus, on the contrary, protecting the dignity and promoting well-being can prevent the tornado caused by the flap of wings and address negative realities, becoming a force for good (Honeyman 2016; Nigri et al. 2017).

In organizations, beneficial social behaviors contribute to efficient business functioning, create a more pleasant work atmosphere, and increase the likelihood of helpful behaviors toward the organization and others (Isen and Baron 1991; Williams et al. 2000; Williams 2004). Many actions on behalf of the company or management can affect the community and the organization positively, from introducing new ways to save energy to returning emails or being coherent.

Leaders should be open to butterfly effects as possible solutions to crises (Strother 2016). A gentle nod of approval can boost morale healthily, and repeated expressions of appreciation can reduce employee attrition more than any complex appraisal system (Varghese 2010). A leader's attitude can subtly shift the organizational direction dynamically and substantially over time (Cummuta 2017) (Fig. 1).

CSR Butterfly Effect,**Fig. 1** Visual representation of the CSR butterfly effect**Summary**

The whole concept of the butterfly effect relies on the notion that everything is part of a more extensive system in which small changes in part of a system can result in more substantial changes to other parts of that system. In organizations, systems consist of people, information, and processes that work together and can best be understood in the context of relationships with each other and with other systems. By viewing problems as parts of an overall system and preparing for butterfly effects as the cause of crises, rather than only reacting to specific events, failures, or process problems can generate insights to understand how changes to parts of the system impact (positively or negatively) other parts of the system within and between organizations (Pensights 2013).

Social responsibility is a factor present in any economic activity, both locally and globally: working conditions can be harmful, pollution can damage the environment and endanger the well-being of the population, marketing strategies can increase unhealthy behaviors related to food and lifestyle, and research can be based on profit-making activities (UNESCO 2010). Thus, to intervene accordingly to create a positive butterfly effect, a systems perspective focusing on cyclical, rather than linear, cause-and-effect relationships is necessary and can be pursued by both management and companies (Pensights 2013).

Social initiatives should be an integral part of the goals of companies and should be integrated into their corporate structure (Nigri and Del Baldo 2018) introducing environmental protection, control, and transparency, accountability, and ethics. At the same current, management goals in organizational strategies should focus on generating prosperity, contributing to a healthy environment and improved well-being so that resources are optimized, negative consequences are minimized, and results are sustained in the long term.

Butterfly effect; Chain of event; Random events

Definition

The butterfly effect is a metaphor that encapsulates the concept of sensitive dependence on initial conditions in chaos theory; namely that small differences in the initial condition of a dynamical

system may produce large variations in the long-term behavior of the system. It is a term that commonly interpreted to mean that small disturbances in the atmosphere may become amplified to give rise to large (or even catastrophic) effects, as might be suggested by chaos theory. The phrase “butterfly effect” was coined by Edward Lorenz, an American mathematician and meteorologist, and a pioneer of chaos theory in 1972 in his paper, *“Predictability: Does the Flap of a Butterfly’s Wings in Brazil Set off a Tornado in Texas?”*.

In the field of corporate social responsibility (CSR), the butterfly effect has become a metaphor for the seemingly insignificant events that can have large, widespread social and environmental consequences. Growing interdependence and interconnectedness have amplified risks and opportunities for consumers, employees, businesses, and governments, particularly civil society organizations. As a result, issues that were once peripheral or local now have global impact. CSR butterfly effect describes how a slight change in initial social and environmental conditions can lead to drastically different outcomes in the worldwide. For example, the flap of a butterfly’s wings in the scandal of sweatshops in Nike in the middle of 1990s was responsible for the boycott and bad reputation all over the world.

The butterfly effect occurs under two conditions: the system is nonlinear and each state of the system is determined by the previous state. In other words, the output at each moment is repeatedly entered back into the system for another cycle through the mathematical functions that determine the system.

Introduction

Chaos Theory and Butterfly Effect

The term “butterfly effect” itself is originally related to the work of Edward Lorenz, based on chaos theory. It was first described in the literature by Jacques Hadamard in 1890 and popularized by Pierre Duhem’s 1906 book. The idea that one butterfly could have a far-reaching ripple effect on subsequent events seems first to have appeared

in a 1952 short story by Ray Bradbury about time travel, although Lorenz made popular the term. In 1961, Lorenz was using a numerical computer model to rerun a weather prediction, when, as a shortcut on a number in the sequence, he entered the decimal .506 instead of entering the full .506127 the computer would hold. The result was a completely different weather scenario. Lorenz published his findings in a 1963 paper for the New York Academy of Sciences noting that “One meteorologist remarked that if the theory were correct, one flap of a seagull’s wings could change the course of weather forever.” Later speeches and papers by Lorenz used the more poetic butterfly. According to Lorenz, upon failing to provide a title for a talk he was to present at the 139th meeting of the American Association for the Advancement of Science in 1972, Philip Merilees concocted “Does the flap of a butterfly’s wings in Brazil set off a tornado in Texas” as a title.

Chaos theory is the study of nonlinear dynamics, where seemingly random events are actually predictable from simple deterministic equations. In a scientific context, the word chaos has a slightly different meaning than it does in its general usage as a state of confusion, lacking any order. Chaos, with reference to chaos theory, refers to an apparent lack of order in a system that nevertheless obeys particular laws or rules; this understanding of chaos is synonymous with dynamical instability, a condition discovered by the physicist Henri Poincare in the early twentieth century that refers to an inherent lack of predictability in some physical systems. The two main components of chaos theory are the ideas that systems – no matter how complex they may be – rely upon an underlying order, and that very simple or small systems and events can cause very complex behaviors or events. This latter idea is known as sensitive dependence on initial conditions, a circumstance discovered by Edward Lorenz (who is generally credited as the first experimenter in the area of chaos) in the early 1960s.

Lorenz in his book “The Essence of Chaos” describes chaos as behavior that is deterministic, or is nearly so if it occurs in a tangible system that

possesses a slight amount of randomness, but does not look deterministic. This means that the present state completely or almost completely determines the future, but does not appear to do so. How can deterministic behavior look random? If truly identical states do occur on two or more occasions, it is unlikely that the identical states that will necessarily follow will be perceived as being appreciably different. What can readily happen instead is that almost, but not quite, identical states occurring on two occasions will appear to be just alike, while the states that follow, which need not be even nearly alike, will be observably different. In fact, in some dynamical systems, it is normal for two almost identical states to be followed, after a sufficient time lapse, by two states bearing no more resemblance than two states chosen at random from a long sequence. Systems in which this is the case are said to be sensitively dependent on initial conditions. With a few more qualifications, to be considered presently, sensitive dependence can serve as an acceptable definition of chaos, and it is the one that we shall choose. "Initial conditions" need not be the ones that existed when a system was created. Often they are the conditions at the beginning of an experiment or a computation, but they may also be the ones at the beginning of any stretch of time that interests an investigator, so that one person's initial conditions may be another's midstream or final conditions. Sensitive dependence implies more than a mere increase in the difference between two states as each evolves with time. For example, there are deterministic systems in which an initial difference of one unit between two states will eventually increase to a hundred units, while an initial difference of a hundredth of a unit, or even a millionth of a unit, will eventually increase to a hundred units also, even though the latter increase will inevitably consume more time. There are other deterministic systems in which an initial difference of one unit will increase to a hundred units, but an initial difference of a hundredth of a unit will increase only to one unit. Systems of the former sort are regarded as chaotic, while those of the latter sort are not considered to constitute chaos, even though they share some of its

properties. Because chaos is deterministic, or nearly so, games of chance should not be expected to provide us with simple examples, but games that appear to involve chance ought to be able to take their place. Among the devices that can produce chaos, the one that is nearest of kin to the coin or the deck of cards may well be the pinball machine. It should be an old-fashioned one, with no flippers or flashing lights, and with nothing but simple pins to disturb the free roll of the ball until it scores or becomes dead.

Chaos surrounds us. Seemingly random events – the flapping of a flag, a storm-driven wave striking the shore, a pinball's path – often appear to have no order, no rational pattern. Explicating the theory of chaos and the consequences of its principal findings – that actual, precise rules may govern such apparently random behavior – has been a major part of the work of Edward N. Lorenz. In "The Essence of Chaos," Lorenz presents to the general reader the features of this "new science," with its far-reaching implications for much of modern life, from weather prediction to philosophy, and he describes its considerable impact on emerging scientific fields.

His theory called the butterfly effect stated that a butterfly could flap its wings and set air molecules in motion that in turn would move other air molecules – which would then move additional air molecules – eventually becoming able to influence weather patterns on the other side of the planet. For years, this theory remained an interesting myth. In the mid 1990s, however, the butterfly effect was proved to be accurate, viable, and worked every time. This is not a science book, but the point is, everything you do matters! Read the butterfly effect story that started with a school teacher from Maine who made one move 150 years ago that impacted an entire nation. He set off a "butterfly effect" that lasts to this day. "Without question, Andy Andrews is one of the most talented writers and speakers in the country. The butterfly effect is a beautiful, unforgettable story that can change the way you look at life. I loved it, and so will you!"

The Butterfly Effect in Corporate Social Responsibility

Lorenz's early insights marked the beginning of a new field of study that impacted not just the field of mathematics but virtually every branch of science – biological, physical, and social. For example, in environment, CO₂ emission of each car and greenhouse gas emission of each factory leads to global climate change; in the financial market, the butterfly effect was certainly evident throughout the financial world during the autumn of 2007 and beyond, as the meltdown of a relatively minor part of the US mortgage market brought global money and capital markets to their knees, while the demise of Lehman Brothers on September 15, 2008, pushed the entire system to the edge of collapse; in biology, a small change in a virus in monkeys in Africa creates a “thunderstorm” of an effect on the human population around the world with the appearance of the AIDs virus, local livestock contaminations (e.g., mad cow disease, avian flu) threaten stability of global health and global food supply chains; in evolution, small changes in the chemistry of the early Earth gives rise to life; and in psychology, thought patterns and consciousness altered by small changes in brain chemistry or small changes in physical environmental stimuli. The butterfly effect is also a common trope in fiction when presenting scenarios involving time travel and with “what if” scenarios where one storyline diverges at the moment of a seemingly minor event resulting in two significantly different outcomes.

In social and environmental science, the late twentieth century has shown that any human and business activity can have very many consequences on society and natural environment – foreseen and unforeseen, intended and unintended, beneficial and catastrophic. The CSR butterfly effect has been amplified by the increasing globalization, new technologies, and a rising tide of expectations among stakeholders about the social and environmental role of business over the past years. The evermore powerful stakeholders, particularly, civil society organizations wield wide influence. For example, since 1990, more than 100,000 new citizens' groups

have been established around the world. The balance of power has shifted in favor of individuals and small single-issue groups increasingly armed with tools and tactics that can easily be deployed through the internet. Trust in nongovernmental organizations (NGOs), citizens' groups, and online information sources have risen as inexorably as faith in business – Enron, WorldCom – has declined. In 1996, Nike found itself at the center of a fury after a New York Times column accused the company of profiting from “sweatshops” of “wretched origin” to create its athletic apparel. Soon Nike was at the center of an international controversy. International labor groups united and over 40 demonstrations occurred at Niketowns and universities across the United States.

The companies as they go global have increasingly encountered social and environmental risk. Globalization offers many opportunities to companies, but also poses novel sources of uncertainty and risks. Multiple business indicators show that the level of uncertainty for corporate leaders has increased, due in large part to:

- Large extended enterprises made up of independent organizations but with tremendous pressures to grow and perform as a unit
- Rapid rates of change in technology, connections, and information flows as a result of globalization
- Problems in managing scale using methods rooted in controlling all decisions across the entire extended enterprise

The result of the greater interdependencies and hidden vulnerabilities that businesses now face is an increased number of uncertainties in corporate decision-making. Current network-based operating models highlight the growing importance of the extended enterprise by establishing greater connectivity among and between stakeholders across the globe. This connectivity has also created entirely new stakeholders and requires innovative forms of risk management.

These changes in the operating model have led to a significant shift in market power – not just to customers and traditional investors but also,

and more importantly, toward stakeholders: communities, employees, regulators, politicians, suppliers, NGOs, and even the media. As a result of this shift in market power, “social risk” is a rising area of concern for global corporations. From a company perspective, social risk, like any other risk, arises when its own behavior or the action of others in its operating environment creates vulnerabilities. In the case of social risk, stakeholders may identify those vulnerabilities and apply pressure on the corporation for behavioral changes. As the ability to listen to corporate stakeholders’ perspectives on social issues becomes a competitive necessity, managing social risks will need to become more fully embedded in corporate strategy.

Globalization entails a paradox: the more interdependent we become, the more we seem to require order and yet foment change. Interdependence (through complexity) brings greater efficiency and effectiveness – but with it comes greater vulnerability. Corporations operating in the global economy are key players in a dynamic system. The higher the number of interactions, both implicit and explicit, that entities have with one another, the more factors are introduced that influence the overall relationship. The dynamic system effectively has more levers and pressure points than existed in the past, many of them critical to smooth operations and playing a role in the optimization of the whole. Those pressure points on business, most notably those pressures by civil society and stakeholders more broadly, constitute social and environmental risk. From a company’s perspective, social risk occurs when an empowered stakeholder takes up a social issue area and applies pressure on a corporation (exploiting a vulnerability in the earnings drivers – e.g., reputation, corporate image), so that the company will change policies or approaches in the marketplace.

From a civil society perspective, a company may well deserve criticism for its social practices. Think of Shell in Nigeria, Nike in Indonesia, oil spills such as the Exxon Valdez, upscale apparel retailers purchasing from sweatshop suppliers, unsustainable forestry practices by the timber industry, or big pharmaceutical companies going

into South African courts to keep imported generic AIDS treatment drugs out of that country, suffering one of the world’s highest HIV prevalence rates. Even where companies break no local laws, they may stand in violation of their own self-proclaimed standards or be accused of breaching international community norms.

Key Issues

Companies that operate in the new global environment need to devise systematic means for dealing with the challenges it poses. One of these challenges as “social risk” could be brought about by the butterfly effect. Civil society organizations in particular can campaign for changes in corporate behavior through protests, boycotts, trying to change purchasing patterns – or, increasingly, partnering with companies to achieve joint aims. The push and pull of these sectors constitutes a butterfly effect, posing both new risks but also opportunities.

A social risk may initially be “picked up” by the CSR antennae; there is no guarantee that is where it will remain. A host of “social risks” have begun as issues that were primarily understood and addressed by CSR departments. However, as those social risks continued to gain attention with civil society, public policy, and media outlets over time, senior managers were also forced to pay attention, as core business operation became impacted. The challenge faced by Nike as a result of conditions in its global supply chain is an example. The case of Nike illustrates more specific dangers of not linking CSR and stakeholder intelligence to core business processes, but also how one company fixed this disconnect to create a win-win outcome.

Therefore, companies should link a comprehensive CSR program (stakeholder engagement) with core business processes (risk management) as part of its overall approach to business performance. As Nike’s experience shows, not linking CSR and related stakeholder intelligence to core business processes can leave a company vulnerable, with no appropriate controls or countermeasures.

Future Directions

The emergence of a social risk brought about by the butterfly effect can have wide-ranging impacts on various aspects of business (from global operations to sourcing to public relations). Any number of stakeholders may transmit a social risk to various divisions in a company. Investors may create shareholder resolutions to change/evolve company policies. Customers may request changes in a company's environmental policies. Employees may raise concerns about outsourcing of jobs overseas. Suppliers may request coverage in a company's healthcare plan. While many of these feedback channels may be familiar to most large public companies, it is emergence of civil society scrutiny, and its resulting social risks, with which many companies are the least familiar and least equipped to manage.

Global companies face a new reality that has changed the nature of risk and risk management: networked operations and global value chains, empowered stakeholders, and the dynamic tension among sectors. The emergence of the new forms of social risk cannot be mitigated through traditional means. The new environment requires innovation by companies in both sensing and understanding these risks, and in adapting risk management systems to include new tools and network-based models of information sharing.

Corporate social responsibility programs are an effective means to provide strategic intelligence for managing social risks. Risk management by global companies should be adapted to include corporate social responsibility programs. CSR provides the framework and principles for stakeholder engagement, supplies a wealth of intelligence on emerging and current social issues/groups to support the corporate risk agenda, and ultimately serves as a countermeasure for social risk. Granted, effectively integrating CSR into core business functions can be difficult, as the experience of Nike illustrates.

Definition/Description

Corporate social responsibility (CSR) is the “integration of an enterprise's social, environmental, ethical and philanthropic responsibilities toward society into its operations, processes and core business strategy in cooperation with relevant

stakeholders” (Rasche et al. 2017). Ethical considerations have risen along with a set of contingent social responsibilities that corporations are now asked to fulfill by society in order for corporations to be deemed sustainable. A key aspect of CSR is therefore accountability and how these activities are communicated to stakeholders. Indeed 93% of the world’s largest 250 corporations currently report on their sustainability performance (KPMG 2017). This information could be provided by annual reports, stand-alone reports, socially orientated advertising, CSR websites, or even social media campaigns. This entry focuses on the key trends in CSR reporting, starting with an introduction to the sustainability reporting context, followed by an overview of the evolution of published CSR reports. This leads into a discussion of the growing use of the Internet to disseminate CSR information through both corporate websites and social media platforms.

Sustainable Development

The Brundtland Report of 1987 provides the classic definition of sustainability as being any activity which “meets the needs of the present without compromising the ability of future generations to meet their own needs” (World Commission on Environment and Development 1987). This is quite an aspirational definition, and it has been argued that it lacks practical and measurable outcomes for corporate implementation. Some years later, however, the sentiment of the Brundtland Report was given new impetus when, in September 2015, all 193 Member States of the United Nations adopted “Agenda 2030” a plan for achieving a more sustainable future for all with ambitions to end extreme poverty, fight inequality and injustice, and protect the planet. These aims are broken down into 17 Sustainable Development Goals (SDGs) which were set following consultation with governments, business, and citizens. It is recognized that all of society has a role to play in achieving these targets; however, given the globalization, size, and power of many corporate bodies, business is considered to have an

important function in achieving these targets, and often sustainability forms part of the CSR reporting remit. Indeed, the terms CSR and sustainability are often used interchangeably, and there is an increasing tendency to refer to the CSR report as the “sustainability report” (Aras and Crowther 2009).

It is widely agreed that future sustainability encompasses environmental, social, and economic aspects, and in a step toward making the United Nations (UN) 2030 Agenda and its SDGs more operationally achievable, the International Standards Organization (ISO) has developed numerous standards and supporting guidance. ISO 26000 is specifically focused on how corporations can operate in an ethical and transparent way, and it requires them to report on how they are addressing stakeholder demands in relation to sustainable development. Corporations can apply to have this certification to verify the quality of the activities currently being undertaken which recognizes the fact that sustainability reporting is increasingly used as a measure of corporate performance and is a value-driving activity.

Another key reporting mechanism when making disclosures on sustainability activities and CSR is the Global Reporting Initiative (GRI). The GRI is the most commonly used reporting framework with 75% of the world’s 250 largest corporates using it in their CSR reporting (KPMG 2017). GRI’s framework for sustainability reporting helps corporations identify, gather, and report on CSR activities in a clear and comparable manner. The GRI framework contains universal standards which can be applied at a foundation level (“GRI101”) moving into more general disclosures which include contextual information about the reporting entity (“GRI102”) and finally the management approach (“GRI103”) which reports on the managerial strategy in respect of each material topic. These material topics will vary according to the level of stakeholder interest, size, and nature of the corporation. Specific guidance on material items is provided under the topics: economic (“GRI 200”); environmental (“GRI 300”); and social (“GRI 400”) development.

The GRI is not just about developing a framework for reporting, it also has an important role in providing advice and guidance to support the framework's implementation. It also works closely with governmental bodies and stock exchanges in developing reporting policies. In 2009, the Sustainable Stock Exchange Initiative was created by the UN with a mission to "build the capacity of stock exchanges and securities market regulators to promote responsible investment in sustainable development and advance corporate performance on environmental, social and governance issues" (Sustainable Stock Exchange Initiative 2019). The legislative environment is also changing, and in December 2014, the European Commission (EC) has introduced a new directive obliging large multinational corporations (those with over 500 employees) to provide nonfinancial disclosures covering environmental-, social-, and employee-related human rights, anti-corruption, and bribery matters. This legislation came into effect in the United Kingdom and Ireland in 2017 with the aim of increasing the transparency of non-financial information in identifying key sustainability risks in order to raise investor and consumer confidence.

The guidance provided by the EC on this directive encourages reporting entities to utilize frameworks such as GRI and ISO26000 when drafting their disclosures. In the United States, corporations are required make climate change-related disclosures in Securities and Exchange Commission filings, and the Sustainability Accounting Standards Board was formed in 2011 which publishes industry-specific Sustainability Accounting Standards that advise what CSR disclosures should be included. These are just some of the moves globally in mandating CSR disclosures in order to encourage corporations to focus on a long-term sustainable approach to their activities. To date there are 42 countries in which the GRI Standards are referenced in government or market instruments, and it is hoped that in today's global business environment, this will help to increase the comparability of reports and lead to more efficient reporting practices (Carrots and Sticks 2019).

The Importance of CSR Reporting

Despite the guidance and regulatory developments discussed above, CSR reporting remains a largely voluntary activity. It is undertaken as corporations recognize that it is one of the key areas through which they can build and maintain relationships with external stakeholders such as customers, suppliers, governments, nongovernment organizations, and unions through continual communication. Much of the research on CSR is concerned with the so-called business case for CSR activities, with academics suggesting that a commitment to CSR is associated with positive consumer relationships; a higher return on investment; the ability to attract, motivate, and retain talented employees; and finally in the investment domain, gaining socially responsible investors (Du et al. 2011). Therefore, CSR without audience support is arguably pointless, and the form of corporate communication used in relation to these activities is key; however, it has been found that despite their successful efforts in developing CSR programs, corporations still have not found appropriate methods of effectively communicating these to their stakeholders (Kesavan et al. 2013).

CSR has been increasingly integrated into the financial reporting remit to assist users in making more informed long-term investment decisions reflecting a tighter coupling between CSR and the corporate's financial goals. Indeed, non-financial disclosures, including CSR and other voluntary disclosures, represent a much larger body of information on corporate activity than financial information in terms of volume and scope. Many corporates include CSR information as part of their annual report and financial statements; others issue a stand-alone CSR report; however, there is a small but increasing trend that has been toward integrated reporting (IR). The International Integrated Reporting Council states that "an integrated report is a concise communication about how a corporation's strategy, governance, performance and prospects, in the context of its external environment, lead to the creation of value in the short, medium and long term" (International Integrated Reporting

Council 2017). IR is more than just combining the disclosure of financial information and non-financial information into one single document. It requires a new way of thinking about how a corporate operates. Instead of narrowly focusing on creating shareholder value from financial capital, a wider view that recognizes the various forms of capital resource available to the business including financial, intellectual, human, social, and natural capital and the utilization of the capital to create shared value for a range of stakeholders is taken under IR. These reports are not “bolt on” or in addition to financial reporting but rather mark a structural evolution in corporate reporting requiring a cultural shift in terms of integrated thinking, overall vision of the business, its risks and performances (financial and nonfinancial), and stakeholder integration. The complexity of this holistic approach to performance measurement is perhaps why only 14% of the world’s biggest 250 corporations choose to report in this way (KPMG 2017).

No matter the medium used for disclosure (annual statements, stand-alone report, or integrated reporting), the voluntary nature of the measurement and reporting of any of these CSR activities makes them open to management manipulation. Any disclosures made will only reflect those aspects of performance that corporations are willing to release. The term “greenwashing” has been coined to describe the selective disclosure of positive information about a corporation’s environmental or social performance while withholding negative information from stakeholders. Arguably if not complying with reporting requirements, the focus of CSR reporting should be to address the users’ information demands; however, there is an expectation gap between the two key parties in CSR disclosures, namely, the preparers and the users. This gap may limit the impact of CSR messages as the recipients may view them as being of little value and be skeptical of what they are being told.

If CSR reporting comes across as excessive self-promotion, it may be met with cynicism and distrust. One way in which corporations can help verify the quality of their nonfinancial reporting is

to obtain external assurance over the quantitative and qualitative disclosures being made, and indeed 67% of the top 250 corporations provide external assurance over their CSR disclosures (KPMG 2017). Studies have shown that investors perceive the report to be more credible where there is external assurance, particularly when this is provided by a professional accountant (Mitchelon et al. 2015). In supporting accountants in this work, the International Standard on Assurance Engagements (ISAE) 3000, *Assurance Engagements other than Audits or Reviews of Historical Financial Information*, was developed by the International Auditing and Assurance Standards Board. ISAE 3000 came into force in December 2003 and is used by accounting firms to guide their assurance engagements on sustainability reports. Any assurance provided is designed to help ensure that the reporting meets stakeholders’ needs and expectations in relation to the disclosures made.

Networked Technologies for CSR Reporting

In addition to assurance, the use of networked communication via websites and social media has been used to make corporate messages on CSR much more credible and acceptable to stakeholders. This is because stakeholders are no longer passively receiving the messages being transmitted to them by corporations, but rather they are empowered to shape and evaluate its content. Through the use of networked technologies, people may interact in a dialogue to collaborate in the creation of content and setting of the corporate agenda. A poll of chief executives from major US corporations revealed 72% reported that social media has been used to communicate to the public about their CSR efforts, and 59% stated that the use of social media has had a positive impact on the quality of their communications with consumers (Kesavan et al. 2013).

The primary value of networked technology such as websites and social media as a dissemination tool for corporate messages including CSR

reporting is its dialogic aspect in engaging stakeholders in the CSR process. It shifts media communication from managing audiences to building and maintaining relationships, which to the end consumer may come as a welcome break from what are at times viewed as elite controlled and hierarchical corporate media structures (Lyon and Maxwell 2011). This provides corporations with a rich source of feedback presenting opportunities to monitor their external environment and better understand and engage with stakeholders in order to avoid or mitigate potential corporate crisis. Indeed, the discourse itself can be construed as positive affirmation of CSR activities, as a corporation's actions have motivated stakeholders to engage.

This dialogue, however, is of limited value until there is an iterative effort from the corporation and change in behavior as a direct response to the issues raised. When the negotiation has resonance with other corporate logics, such as value creation, then co-construction of the CSR agenda may result. Indeed, networked technologies have transformed the potential role of communication from dissemination of CSR activities to a joint co-creation of CSR strategy between managers and stakeholders called CCO (Communication Constitutes Organisation) in recognition of the ability of communication to influence a corporation (Schultz 2013). The first step a corporation has to take to enter dialogue and engage in CCO is providing the opportunity for stakeholders to do so across communication platforms such as corporate reports, websites, and social media.

Summary

Although the CSR agenda is set and measured internally by corporations, it is inherently stakeholder driven, and therefore stakeholder awareness and managing stakeholder feedback are key to reaping the strategic benefits of any CSR initiatives undertaken. Arguably the true benefits of nonfinancial reporting will be felt only when it is properly integrated with financial reporting and not treated as a separate activity. Ultimately

reporting is only an instrument; the benefits from CSR activities will come when they are fully embedded in the business, which reporting can demonstrate but cannot achieve on its own.

Definition

CSR Communication

CSR communication involves communicating by companies and other organizations to a broader range of interest groups apart from shareholders and creditors, including employees and even society as a whole about social, economic, and environmental aspects of the organization's performance rather than profit and financial position alone.

Annual Report

An annual report is a comprehensive report on company's activities throughout the preceding year. The single source of getting information about any company is their annual report because an annual report communicates to different stakeholders about a company's financial as well as nonfinancial performances.

Introduction

With the rapid spread of globalization, business leaders have begun to realize that we live in an interconnected world where mutual interdependence is the basis of our existence as well as our progress. For the survival and sustained growth of business itself, organizations have realized that it is essential not to limit their

thoughts and concerns within the boundary of the organization. Organizations have realized that longevity of any corporation requires it to earn the goodwill and this goodwill can be achieved by showing its responsiveness toward social responsibility. This would help them to build up a reputation which in turn would have a positive impact on their business. Hence CSR today is not just a part-time philanthropic activity but a strategic imperative directly linked to business results for long-term sustainability of organizations (Ghosh 2016). Constant information flow and growing social and environmental consciousness uphold corporate social responsibility (CSR) more as a business necessity than a mere option.

Communication of accurate, comprehensive, and timely information is important for efficient functioning of a capital market. With the emergence of corporate governance and various disclosure norms across the world and with the emergence of International Integrated Reporting, it has become important to study not just what is being communicated but how it is being communicated as well. In other words, both form and content of the communication are important. In fact, creative communication (presence of striking, relevant, and understandable content) is essential for a CSR communication plan. However, the communication of CSR practices is not merely transmission of information (i.e., objectives, intentions, activities); it goes beyond that because it is based on a continuous process of exploration, construction, negotiation, and modification among different actors (Christensen and Cheney 2011).

With modern communication technologies enhancing the scope of availability of information, stakeholders from all walks of life are making more informed decisions. Measures to communicate CSR efforts are now an essential part of businesses especially for a country like India where CSR communication has become mandatory. For a business to succeed, not only does a company have to engage in CSR, but they must also find ways to communicate their CSR endeavors to stakeholders in forms that resonate with them.

CSR Communication

Understanding the Concept

CSR communication has become a vital issue in building and sustaining the legitimacy of a company in the eyes of stakeholders. According to the definition provided by Podnar (2008), CSR communication is a process of anticipating stakeholders' expectations, articulation of CSR policy, and managing of different organization communication tools designed to provide true and transparent information about a company's or a brand's integration of its business operations, social and environmental concerns, and interactions with stakeholders. Recently, there have been many efforts made by authors globally to understand, explain, and justify CSR communication in terms of theories drawn from social and political theory. These theories can be seen as encompassing the *stakeholder theory* (Ullmann 1985), *legitimacy theory* (Lindblom 1984; Guthrie and Parker 1989; Patten 1992), *accountability approach* (theory) (Gray et al. 1987), and *political economy theory* (Cooper and Sherer 1984).

According to Ullmann (1985) with respect to *stakeholder theory*, organizations should regard social responsibility activities as an active management strategy; then only can one expect a positive relationship between stakeholder power, social performance, and social communication. In discussing the *legitimacy theory*, which is considered to be the dominant theory in the CSR communication research, one can see that it is based on the concept of social contract (Lindblom 1984; Guthrie and Parker 1989; Patten 1992; Hooghiemstra 2000). A company needs to engage in proactive CSR communication for society to regard it to be a good citizen (Guthrie and Parker 1989). For the purpose of legitimizing its actions, a company needs to justify its continued existence (Lehman 1983, from Guthrie and Parker 1989). As far as the *accountability theory* is concerned, Jackson (1982) regarded accountability as "explaining or justifying what has been done, what is currently being done and what is planned . . . [and]. . . involves therefore, the giving of information." Hence it can be the most useful ideological framework for analyzing communication of accounting information in

general and CSR disclosure in particular. There are a lot of limitations involved in the present system of accounting and accounting reports (Cooper and Sherer 1984) because it disregards social welfare and is biased toward the shareholders. However from the *political economy theory* perspective, accounting reports can be perceived as a tool for communicating social, political, and economic facets of a firm. The basis of all the theories that has developed so far speaks of the fact that, for corporate enterprises, the capacity to influence the CSR activities taken up by them depends on the capacity to communicate with different stakeholders and on the support obtained from them. Hence CSR communication has become crucial in today's scenario.

Benefits of CSR Communication

CSR communication enhances corporate image and its reputation. It not only helps to improve relationship with the whole gambit of stakeholders, but it helps to attract better skilled employees (Branco and Rodrigues 2006). Regular CSR communication enhances transparency by increasing the awareness about CSR activities and ensuring corporate transparency. It helps in supervision of CSR activities and thus discovering the weaknesses in CSR corporate strategy. CSR communication accelerated involvement of stakeholders by strengthening their position and their involvement in company decisions. It also supports cross-sector partnerships between businesses, government agencies, and nonprofit organizations (Vexlerova 2008).

Annual Report

Understanding the Document

According to Le Breton-Miller and Miller (2009), investors' and other stakeholders' decisions are largely influenced by the quality of information presented in annual reports. The single source of getting information about any company is their annual report because an annual report communicates to different stakeholders about a company's financial and nonfinancial performances, past or present performance, a

company's mission and vision, detailed financial performance through the financial statements, corporate governance or CSR activities, a company's strategy, risk management policies, and the future outlook. It is a report that every company must provide to its shareholders' at the annual general meeting. Rather it is a report that every investor must read. It is the most comprehensive means of communication between a company and its stakeholders, rightly called the pinnacle of corporate communications (Cohen 2002; Coy and Dixon 2004; Li 2008; Linsley and Shrivs 2006; Santema and van de Rijt 2001).

Purpose of an Annual Report

- Provides financial information – The financial information provided in the annual reports helps determine the current status of business, how the company is funding operations and growth, and how good the company is placed at making money for its investors.
- Accountability – Through the annual report, we can have an idea about how far the company has met its responsibilities and the financial reports which form a part of the annual report reflects the extent of performance of the organization.
- Decision making – The performance of the company that gets reflected in the annual reports helps a wide range of potential users for evaluating and making economic decisions.
- Promotion of the company – Inclusion of positive feedbacks from employees and customers or key developments of the company which are highlighted increases the readership of the report and appeals to new investors and customers. Thus the shareholders and stakeholders feel good about their investments in that company.

Key Constituents of Annual Report

The major components of the annual report reflect on the transparency and credibility of the company, giving a fair idea on the sustainability of business and how sound the business is. The major components are:

- Letter from the Chairman
- Ten-year financial summary
- List of directors and other officers
- Management discussion and analysis (MD&A)
- Director's report
- Corporate information
- General shareholders' information and corporate governance
- Financial statements and schedules

CSR Communication, Annual Reports, Indian Companies Act 2013

With the enactment of Section 135 of the Companies Act, 2013, India became the first country to include provisions of CSR in Company Law and make CSR expenditure mandatory for organizations based on pre-specified criteria. CSR is still a voluntary exercise left to the discretion of the organization in the rest of the world. However an encouraging aspect is that a growing number of countries have made communication of CSR activities undertaken by corporate mandatory. Thus, in countries such as Sweden, Norway, the Netherlands, Denmark, France, Australia, and China, either government regulations or stock exchange regulations or both require corporate to disclose their CSR activities through sustainability reporting. The distinguishing feature of Section 135 is that it not only makes communication of CSR activities mandatory but goes a step further to mandate CSR activities in the first place.

CSR activities undertaken by corporate in India can be communicated through annual reports via the following segments:

- *“Chairman Message”* – Even though this segment is voluntary in nature, CSR activities can be communicated via this segment.
- *“Separate section for CSR”* – Similarly even though this segment is voluntary in nature, CSR activities can be communicated via this segment.
- *“Director's report”* – This segment is mandatory as per Section 134 of the Company Act of 2013 and Regulation 34(2) (f) of SEBI

(LODR) Regulations 2015. CSR communication via this segment is mandatory.

- Rule 8 of the Companies (Corporate Social Responsibility Policy) Rules, 2014 provides the following:

The Board's Report of a company covered under these rules pertaining to a financial year commencing on or after the 1st of April 2014 shall include an annual report on CSR containing particulars specified in Annexure (Annexure 1). In case of a foreign company, the balance sheet filed under Section 381 (1) (b) shall contain an Annexure regarding report on CSR (Annexure 1).

Section 134(3) (o) of the Companies Act of 2013 requires that the report by the Board of Directors shall include the details of the policy developed and implemented by the company on corporate social responsibility initiatives taken during the year. If the company fails to spend 2% of average net profits during a financial year, the Board shall, in its report, specify the reasons for not spending the amount.

- “*Management discussion and analysis*” – This segment is mandatory as per Regulation 34(2) (f) of SEBI (LODR) Regulations 2015. It usually forms a part of the directors' report in an Annual Report or is an addition thereto. Majority of the organizations communicate

about their CSR activities via this segment as well.

- “*Business Responsibility Report*” (BRR) – SEBI has mandated inclusion of Business Responsibility Report (BRR) as a part of the Annual Report for top 500 listed entities as per Regulation 34(2) (f) of SEBI (LODR) Regulations 2015. Business Responsibility Report describes the initiatives taken by the listed entity from an environmental, social, and governance perspective. It forms a part of the annual report as specified by the Securities and Exchange Board of India, and it is prepared according to the format as specified by them (Annexure 2).

Key Issue

Although the annual report serves as a communication tool, its success shall be determined on the quality of information provided therein. That is why it is important to study not just how CSR information is being communicated but what is being communicated in order to gauge its relevance.

Format for the Annual Report on CSR

Activities to Be Included in the Board's Report

1. A brief outline of the company's CSR policy, including overview of projects or programs proposed to be undertaken and a reference to the web-link to the CSR policy and projects or programs.
2. The Composition of the CSR Committee.
3. Average net profit of the company for last 3 financial years.
4. Prescribed CSR Expenditure.
5. Details of CSR spent during the financial year:
 - (a) Total amount to be spent for the financial year;
 - (b) Amount unspent, if any;
 - (c) Manner in which the amount spent during the financial year is detailed below:
6. In case the company has failed to spend the 2% of the average net profit of the last 3 financial years or any part thereof, the company shall provide the reasons for not spending the amount in its Board report.
7. A responsibility statement of the CSR Committee that the implementation and monitoring of CSR Policy, is in compliance with CSR objectives and Policy of the company.

Annexure 2

Format for Business Responsibility Report

Section General Information about the company

Section B – Financial Details of the Company

Section C – Other Details

Section D – BR Information

1. Details of Director/Directors responsible for BR
2. Principle-wise (as per NVGs) BR Policy/policies

3. Governance related to BR

Section E – Principle – wise Performance (Principle – wise Performance further contains Principle 1 to Principle 9)

Principles to assess compliance with environmental, social and governance norms

Principle 1: Businesses should conduct and govern themselves with Ethics, Transparency and Accountability

Principle 2: Businesses should provide goods and services that are safe and contribute to sustainability throughout their life cycle

Principle 3: Businesses should promote the wellbeing of all employees

Principle 4: Businesses should respect the interests of, and be responsive towards all stakeholders, especially those who are disadvantaged, vulnerable and marginalized

Principle 5: Businesses should respect and promote human rights

Principle 6: Business should respect, protect, and make efforts to restore the environment

Principle 7: Businesses, when engaged in influencing public and regulatory policy, should do so in a responsible manner

Principle 8: Businesses should support inclusive growth and equitable development

Principle 9: Businesses should engage with and provide value to their customers and consumers in a responsible manner

CSR Communication and Perspective

Huriye Toker

University of Yasar, İzmir, Turkey

Synonyms

Corporate communication; Organizational communication; Stakeholder communication; Strategic sustainability communication

Definition

In the current era, because a variety of stakeholders are demanding information about companies' Corporate Social Responsibility (CSR) activities, a CSR communication strategy is essential for business survival. Information supply has evolved from a strict, one-way company-controlled exercise toward a more interactive and even digital approach with online communication possibilities to a mass audience. Twenty-first-century corporate communication tools seek feedback from various stakeholders before trying to meet their demands through appropriate CSR communication. However, effective, strategic, tailor-made, and interactive communication remains the missing link in the practice of corporate responsibility. Today, companies need to differentiate their CSR communication tools according to the stakeholders, including online and traditional communication devices.

Introduction

The generally accepted CSR definition is “the voluntary efforts of enterprises to integrate social and environmental considerations into their activities and their interaction with all stakeholders” (European Commission 2001, p. 6). Another definition describes CSR as a voluntary commitment of business to exceed explicit and implicit social obligations (Parker 2008, p. 84). Although there is wide recognition regarding the importance of

CSR Communication and Perspective, Fig. 1 CSR stakeholders. Adapted from Kanji and Chopra (2010) and Hohnen and Potts (2007)

CSR, there is no consensus on its definition due to its varied nature (Turker 2018, p. 3). While research currently emphasizes different aspects of the phenomenon, the mostly highlighted reality is the global focus on CSR communication efforts. CSR communication is defined as the “building and maintaining of favourable reputations and relationships with key stakeholders” (Cornelissen 2004, p. 17). These stakeholders are both individuals and groups who can influence company decisions. As shown in Fig. 1, the basic stakeholders are government, local communities, employees, NGOs, trade unions, consumers, and shareholders, which have different levels of impact on companies. Currently, including stakeholders in CSR communication has been increasingly valued and accepted as a civic business attitude.

Communication outcomes vary depending on stakeholder characteristics (Toker 2013). Communication comprises message, content, and channel, which define the success of CSR communication outcomes (Fig. 2). Awareness and trust can be categorized as internal communication outcomes while loyalty, purchases, productivity advocacy, and amount of invested capital for investors are external

outcomes. Impact and the commitment are related to the content of CSR communication messages.

CSR communication channels and tools are the most essential elements of a CSR communication strategy. These are used in worldwide depending on corporate culture and country characteristics. Communication tools range from CSR reports, corporate website announcements and media coverage to sponsorship and PR activities, advertising and word of mouth. Although some communication tools, such as public relations and advertising, are more powerful and effective, they are not viewed positively by some stakeholders, such as consumers and NGOs (Jahdi and Acikdilli 2009, p. 106).

The Changing Nature of CSR Communication

A lot has changed since the powerful argument of economist Milton Friedman (1970) that related CSR with profit maximization in business. Now that this view no longer prevails, CSR has been a rapidly increasing practice, with businesses becoming increasingly interested, active and innovative.

Framework of CSR Communication

CSR Communication and Perspective, Fig. 2 Framework of CSR communication. Source: Adapted from Tonello (2011)

The phenomenon has appeared on the boardroom agenda in many organizations. Therefore, CSR communication has also evolved and entered a new stage. Certain characteristics need to be highlighted regarding the changing perception of CSR communication:

- *Varied information demands of stakeholders regarding CSR actions of business:*

As an important stakeholder of the CSR communication strategy, **consumers** not only expect businesses to be socially responsible but they also want to be informed about what companies are doing in the CSR field. “More information on a company’s social and ethical behavior would influence their purchasing decisions, therefore companies actively communicate their CSR activities” (Pomeroy and Dolnicar 2009; Dawkins 2004; Environs 1999). For example, in 2007, 97% of the largest firms in Europe communicated on corporate responsibility issues in their websites (Borglund et al. 2008). After the information phase, since CSR communication is a circular

process, companies continuously evaluate and respond to stakeholder attitudes and demands. However, this process needs a well-designed communication strategy and implementation of organizational communication based on stakeholder expectations, which is theoretically called the stakeholder involvement strategy.

Organizations should not underestimate the word-of-mouth communication channel of another important stakeholder group: **employees**. Because of social ties and wide reach, they are often considered a source of credible information. Thus, companies should include this group in their internal CSR communication strategy and find ways to convert them into CSR advocates.

Another important and specific stakeholder group, **NGOs, consultants, analysts, and investors**, act as counterparts to corporations. To communicate with this group, the company needs more professionalized and tailored action (Frostenson et al. 2011). Thus, CSR communication is also criticized for being aimed just at professionals through CSR reports. However, although CSR reports are an important tool to communicate with

opinion leaders and NGOs, CSR communication should also include the general public and consumers generally as its target audience. **The media** is another important stakeholder in the communication strategy. It may be skeptical about company messages and there may be potentially hostile reactions from the media, campaign groups, and others. However, despite these skeptical relations, getting positive media coverage on television or in the press, such as in *Business Ethics* or *Fortune* magazine, is much more effective than paid advertising. The diverse information requirements of different stakeholder groups also present special communication challenges.

- *CSR communication strategy should be carefully designed*

Besides the stakeholder information strategy, stakeholder response and stakeholder involvement strategies are the two other CSR communication strategies. For effective CSR communication, they define CSR as a circular process combining information, involvement, and response strategies. Therefore, to communicate CSR professionally, companies need to inform stakeholders about their CSR efforts as well as to simultaneously and continuously evaluate and respond to stakeholder attitudes and demands. Thus, communication becomes a circular, on-going process. This mechanism is important for at least two reasons. First, it might increase the accuracy of information by reducing information asymmetry among the parties. Additionally, it can ensure the transparency of the communication process with internal and external stakeholders.

Communication channels should be carefully chosen according to the CSR communication strategy. A company can communicate its CSR activities through official documents, such as annual CSR reports, website announcements, or press releases. It can also use traditional media tools, such as TV commercials, magazine or billboard advertisements, or use social media alternatives, even B2B communication possibilities, depending on the strategy and target group. In considering the best channel and the most effective CSR strategy,

communication includes the appropriate use in time and place of both traditional (e.g., CSR reports, press conferences, brochures, presentations advertisements) and technology-driven tools (e.g., CSR electronic forums, e-mails, web forms, website FAQs, blogs, electronic newsletters, Intranets, and audio and video podcasts). Among the different communication alternatives, CSR reporting and official company websites are the most common tools to disseminate CSR-related information to various stakeholder groups. Apart from CSR reporting, however, other traditional communication tools, such as personal contacts, public meetings, interviews, workshops, presentations, and business dinners, are considered “outdated” (Isenmann 2006, p. 253). Nevertheless, traditional tools still can be effective within a well-designed CSR strategy to support the overall communication strategy and remain appropriate for certain stakeholder groups.

- *CSR communication strategies should develop with technology:*

CSR communication is currently moving away from simply organizing press conferences or providing glossy brochures toward an advanced interactive, transparent, and dynamic approach with Internet-based tools, including e-mail, web forms, blogs, electronic newsletters, customer-provided web content, and Web 2.0 social media applications. Individualized online tools tailored to the target group, such as reports, brochures, press releases, newsletters, and presentations, are available to everyone in the public sphere (Toker 2013). As a result, companies need their CSR communication with different stakeholders to become more interactive and creative. Thus, information supply and dissemination have evolved from a one-way, company-controlled practice toward a more interactive approach. The Internet-based advanced CSR communication ensures online availability of external CSR documents, feedback possibilities through regular updates, easily accessed contact details, and automatic order forms. Other traditional communication tools, such as personal contacts, public meetings, presentations, and business dinners, are still effective and organized, yet have

limited ability to reach today's mass audiences (Isenmann 2006).

Summary

In his famous definition, Carroll (1979, p. 500) claims that the "social responsibility of business encompasses the economic, legal, ethical, and discretionary expectations that society has of organizations at a given point in time." Thus, he suggests integrating companies' social, environmental, ethical human rights, and consumer concerns into their business operations. Increasing competition in the business world and pressure from governments or society all require a stakeholder perspective to doing business. Companies must respond to the demands of all groups with legitimate stakes in the organization, from consumers and employees to the media or even future job applicants. To deal with this variety of stakeholders and their demands, communication is the natural linchpin (Turker and Toker 2017, p. 163) within the sustainability and social responsibility framework, known as CSR today. Because CSR is a very delicate matter, a key challenge is to minimize stakeholder skepticism and to convey favorable corporate motives in a company's CSR activities. In order to overcome stakeholder skepticism regarding CSR, a successful CSR communication strategy is essential for every company (Du et al. 2010).

The key issues related to CSR communication include questions surrounding what to communicate (message content), where to communicate (message channel), how to communicate (loud or salient communication tools), as well as an understanding of the company- and stakeholder-specific factors that impact the effectiveness of CSR communication.

A company should emphasize the convergence of social and business interests, and frankly acknowledge that its CSR endeavors are beneficial to both society and itself (Porter and Kramer 2002). There are a variety of communication channels through which information about a company's CSR activities or record can

be disseminated. Besides these communication channels, a company can focus on its commitment to a social cause in various ways, including donating funds, in-kind contributions or providing other corporate resources, such as marketing expertise, employee volunteering, and research and development capability dedicated to a cause.

Regardless of the good intentions of the company's CSR commitment, however, its CSR projects and other related philanthropic activities may be criticized as a form of PR and a marketing tool for promoting the company's image through cause-related marketing (Porter and Kramer 2002). Thus, some commentators label it as "window dressing," "hype," or a "fad" (Economist 2005; Cetindamar and Hopkins 2008, p. 402). Nevertheless, despite these harsh criticisms of CSR awards or celebrations of different institutions, a persistent emphasis on CSR projects in company interviews will lead and shape media interest, thereby contributing to the future perception of social responsibility.

Today, most companies need creative communication solutions to disseminate their corporate responsibility messages in a striking, relevant, and understandable way (Dawkins 2004). Moreover, due to the sensitive nature of CSR communications, CSR activities cannot be advertised in the same way as products or services (Pomeroy and Dolnicar 2009, p. 288), with consumers preferring less aggressive and "silent" channels, such as annual reports and websites.

However, while some organizations can take advantage of their social and sustainability concern, others cannot build their own "business case" at all. This significant variability among firms is partly related to each company's overall communication strategy. That is, it is not usually related to the amount or quantity of communication; rather, it is mainly related to how effectively they communicate such involvement (Dawkins 2004; Morsing and Schultz 2006). Different aspects of CSR communication, from message content and communication channels to company- and stakeholder-specific factors influence the effectiveness of CSR communication.

Future studies need to investigate how a company can best communicate its CSR initiatives to specific target audiences. CSR communication is a long-term process that requires an organizational awareness of internal and external stakeholders' changing expectations and demands. This in turn entails establishing sound communication externally and internally, depending on the cultural and organizational framework of the country.

The most important communication tasks are to design coherent and appealing messages, and then communicate them effectively to the general public and stakeholders. The new era needs well-designed and creative communication alternatives with the help of new media technology, although CSR reports still have an undeniable importance for all stakeholders.

CSR Disclosure Quality: Role of NEDs

Kemi C. Yekini

Synonyms

Board independence; Nonexecutive directors; Stakeholder communications; Sustainability reporting quality

Definition

Myriad studies have documented that organizations with more nonexecutive directors (NED) disclose higher quality information than others (Yekini et al. 2015, 2017). For example, Yekini et al. (2015) examined the impact of board composition on corporate community involvement disclosure (CCID) for a sample of UK-listed companies and found that having more NEDs on the corporate board enhances corporate social responsibility (CSR) disclosure quality. This finding provides insights to policymakers who are desirous of achieving optimal board composition. The finding also broadens our perception of the firm's interaction with its corporate and extended environment through high-quality disclosures.

Introduction

Besides having corporate boards composed of individuals that bring substantial experience, expertise, and skills, such as accountants, lawyers, as well as finance and marketing experts, corporate boards consist of community leaders. Studies such as Yekini et al. (2015) and Hillman et al. (2000) documented that community leaders are very crucial nonexecutive directors (NEDs) to corporations because they possess extensive experience and information that could guide the corporation on the impact of organizational activities on the society at large and its relationships with influential community groups. Having such community prominent figures on board is regarded as a strategic move because of the need for firms to adapt to the uncertain business environment by allowing ideas and suggestions from nonbusiness perspectives. In addition, such board composition consisting of NEDs is crucial to providing strategic direction such as utilizing the directors' influence on various community groups. Similarly, their presence on the board has been found to enhance corporate disclosures (Yekini et al. 2015). This explains the significant increase in regulation and corporate governance reforms that focused mainly on board composition.

Key Issues

In today's business world, corporate disclosures, especially CSR reporting, remain a valuable tool employed by corporations as evidence of corporate legitimacy. This is because CSR information is intended to communicate to stakeholders the intrinsic values of the organization (Yekini et al. 2021). It helps to clarify issues that could otherwise bring about distrust between a firm and its key stakeholders resulting from poor communication. Consequently, companies have to continuously maintain their societal legitimacy by strengthening their community recognition through effective communication with the community within which it operates and engagement with the community leaders. Neglecting these

could result in reputation risk to the firm. It is therefore important to mitigate the threats to reputation through frequent interaction between the company and its conferring public. To this extent, the literature recognizes the growing importance of high-quality CSR disclosures and has therefore sort to understand the impact of board composition on CSR disclosures (Yekini et al. 2015). The argument is that the composition of the board of directors where NEDs are well represented provides a crucial tool in enhancing the quality of CSR disclosures. This is because NEDs are seen as community leaders whose responsibility is to raise the concerns of their community at the board level and to maintain good relationships among their local community, the corporation, and the government. In addition, community representatives on the board provide an opportunity for firms to appreciate the impact of corporate action on the community of operation and consequently lead to modification in corporate strategy. This will in turn improve the interactions between the firm and the community within which it operates. Furthermore, addressing the issue of governance structure and the emphasis on increasing the representation of NEDs in the governance process is very crucial in meeting the recent global demand for transparency in governance and accountability.

Future Directions

The majority of studies on the impact of community influential NEDs on corporate disclosures have focused on disclosures in annual reports. However, given the advancements in, and the use of other communication media such as Twitter, Facebook, and other social media outlets, it will be interesting to examine the influence of NEDs on the quality of information released through these media. Future research may also explore other regions especially emerging economies with little or no corporate governance structure in place. Such markets and institutions are informal and quite distinct from those in developed economies such as the

UK or USA. More research is required to investigate the relationship between corporate disclosure quality and NEDs using samples from emerging economies.

Classification; CSR report quality; Definition;
Dimensions; Evaluation; Sensemaking

Definition

Over the decades, there has been growing contention on how to define or measure disclosure quality. Scholars such as Beattie et al. (2004), Beretta and Bozzolan (2008), Yekini and Jallow (2012), and Yekini et al. (2015) all documented varied definition constructs and measurements of disclosure quality including describing disclosure quality as a problematic concept to construe. However, looking at disclosure quality from the perspective of the users of the reports, Yekini et al. (2021) provided a definition that looks at CSR disclosure quality from the context of sensemaking, arguing that the ability of users to draw meaning and the sense they can make out of the disclosed information should characterize the measure of quality (Yekini et al. 2021, pp. 879). Defining disclosure quality this way, therefore, raises some fundamental questions regarding the varied quantitative measures employed in previous studies.

Introduction

Extant literature documented diverse measures of disclosure quality. Some scholars measured quality by relying on certain criteria in the annual reports, for example, evidence disclosed or the nature or themes of the disclosure. Others believe that the location of the information could be indicative of its quality. Similarly, some authors used the volume of disclosure as a measure of quality;

they argued that the quantity of information can influence the quality. Furthermore, while some used analyst ratings, others constructed their own index by taking into consideration a combination of the various criteria. Nevertheless, the validity, scope, reliability, and comparability of the various measures have been queried and of concerns not only to researchers but also to corporate stakeholders, such as regulators, investors, and the media among others. Similarly, scholars have engaged in research relating to quality and reliability over the years. They seek out the best approach and measure for the quality of CSR reports given the narrative nature of the reports (Yekini et al. 2015). They questioned the cogency of the quantitative measures employed by previous studies. Some of the issues raised are whether CSR disclosures should be measured in terms of their quantity (i.e., their volume or their length) or their quality (i.e., their authenticity or reliability). And, if we decide on measuring its quality (authenticity or reliability), what should be the best measure or the best way to measure quality?

Key Issues

A thorough review of extant approaches to the measurement of CSR disclosure quality reveals that measuring the quality of CSR disclosures would depend on several factors. For example, Yekini and Jallow (2012) and Yekini et al. (2015) provided extremely useful criteria for quality measures. First, they considered the nature of the disclosure, whether financial, physical, or narrative. They defined physical as the display of verifiable evidence, for example, a photograph of the CSR theme such as a community project displayed to support the narrative or financial disclosure on community projects. Further, they considered the relevance of the disclosure, which they measured by the section of the annual report the disclosure is located. Gray et al. (1995) argue that the chairman's statements, for example, being a strategic section of the annual report, would usually contain information considered to be of high importance and of which management intends to have it widely read. Similarly, Yekini

and Jallow (2012) argued that specificity rather than quantity should characterize the quality of disclosures, that is, providing detailed description of the specific CSR activity is considered more important in measuring the quality of such disclosure. They argued further that, to measure disclosure quality, there is the need to adopt a weighting system whereby higher scores are assigned to verifiable disclosures and lower scores to narratives that have little or no substance in them (Yekini and Jallow 2012). However, extant literature did not provide a consensus on the allocation of points to disclosure quality classifications. Although Yekini and colleagues were able to justify their differential weighting scheme, arguing that classifications have different levels of information, while some contain more information, others contain fewer. Nevertheless, some schools of thought believe that scoring system is suitable only for the measure of the extent of disclosure as opposed to the quality of disclosures due to their subjective nature. In the last decades, however, this viewpoint has led to conflicting findings on the content and quality of CSR reports (Yekini 2017). The construct validity of the various measures used in the literature has been the subject of debates and contentions. The argument is that these various approaches lack fundamental theoretical conception and methodology. Price and Shank (2005, p. 90) believe that a comprehensive approach to measuring disclosure quality should take into consideration the point of view of the recipient of the information. Similarly, Yekini et al. (2021) argued that the focal point of quality measure should be the sense that users are able to make of the information. Sensemaking involves being able to conceptualize organizational values, which are otherwise incomprehensible, in a way to influence the perception of users of the information. Coupland and Brown (2004, p. 1328) described organizational values as *linguistic social constructs* and maintained that the best way to evaluate such constructs is through dialogical processes. Consequently, Yekini et al. (2021) proposed semiotics (a linguistic-based methodology and analytical tool) as a useful approach to examining the quality of CSR reports.

Future Directions

Research on measuring and defining CSR disclosure quality is gradually shifting focus toward the meaning or sense that the users of the reports can draw from the reports and the usefulness of the reports to the users. This was clearly illustrated in Yekini et al. (2021), through the application of semiotics, a linguistic analytical tool. Certainly, the need for a linguistic methodology in drawing meanings and thus making sense of corporate disclosures is very vital to the determination of CSR disclosure quality. However, advancement in technology, artificial intelligence (AI), and machine learning is beginning to redefine future research in this area. The application of AI is rapidly gaining ground in text analysis and mining and has become a very powerful tool for investigating human cognition and therefore disclosure quality measurements.

Definition/Description

Corporate social responsibility (CSR) rests on the premise that businesses and societies are interdependent. Businesses draw resources from the common pool and have to contribute back in terms of products and services for the members of society. In doing so, they have to act responsibly. Emerging markets are those economies that are on the trajectory of growth that is faster than other developing countries but they have yet to attain the developed economy status. There are certain defining characteristics of emerging markets that make them attractive destinations for investment. They also have some unique challenges facing them. CSR and emerging markets make a difficult combination as there are pros and cons of applying CSR in the context of emerging markets. CSR in emerging markets generally follows the global trends yet there are certain special features of CSR in individual emerging markets that make them unique.

Introduction

Corporate social responsibility (CSR) is a popular term and acronym that could mean different things to different people. The idea of CSR rests on the logic that business and society are

interdependent. The society is the source for resources and legitimacy to business. The business, on its part, must act in a responsible way and not harm the society and the natural environment. It should also strive to contribute to society and its members. When it does, the business can be considered as socially responsible.

There are several definitions of CSR. The definition of CSR from the World Business Council for Sustainable Development (WBCSD) states that it is “the continuing commitment by business to behave ethically and contribute to economic development while improving the quality of life of the workforce and their families as well as of the local community and society at large” (WBCSD 1998).

The definitions of CSR often refer to five dimensions of social, economic, environmental, stakeholder, and voluntarism. CSR is viewed from the perspective of its various dimensions, particularly the first three dimensions of social, economic, and environmental responsibilities to stakeholders. These responsibilities are generally performed voluntarily.

To understand the concept of CSR one could also see its explanations by international agencies. United Nations Industrial Development Organisation describes CSR as “a management concept whereby companies integrate social and environmental concerns in their business operations and interactions with their stakeholders. CSR is generally understood as being the way through which a company achieves a balance of economic, environmental and social imperatives (‘Triple-Bottom-Line- Approach’), while at the same time addressing the expectations of shareholders and stakeholders” (UNIDO n.d.).

CSR is not a new phenomenon. It is a long established idea that people endowed with wealth and resources should conduct themselves in a socially responsible manner. CSR has been practiced in various forms since ancient times. Individuals and organizations involved in trade, commerce, and business have voluntarily or involuntarily discharged social responsibilities. Traditional forms of CSR have often been philanthropy, charity, and community relations. Since a long time, businesspeople having acquired wealth

and sought social approval and higher status within society through philanthropic acts, giving charity, and spending money on furthering community relations.

CSR is now a global phenomenon and movement with significant differences in the regions of the world. In recent years, voluntary initiatives in CSR have been a major trend in international business. There are several other significant developments including the setting up of organizations related to CSR voluntary work, consultancy firms specializing in CSR, growing interest in the investment community about CSR, and the growth of CSR as an academic discipline in higher education.

The Emerging Market

Traditionally, the world has been divided into types of economies based on the level of development measured by per capita gross national income. There are the developed economies such as Germany, Japan, and the United States. There are developing economies such as South Africa, Brazil, China, and India. Then there are the least developed economies most of them in Asia and Africa such as Cambodia and Ethiopia. Among the large number of developing economies are those that are growing relatively faster than the others and have a vast market. Such economies are referred to as the emerging market economies or emerging markets.

The term “emerging market” or “emerging market economy” is a popular term. The term was coined by economists at International Finance Corporation, a division of the World Bank, in 1981, while they were preparing to promote the first mutual fund of equity markets in developing countries. Since that time, the term has become widely known and is used frequently in media, foreign policy lexicon, investment fund industry, and references to multinationals. The word “emerging” has come to indicate those economies that have been growing fast in recent years. By 2030, emerging market economies are likely to account for 62% of total growth in global consumption, the equivalent of \$15.5 trillion in

spending. The growth is unequal with some developing countries developing faster than others.

There are certain defining characteristics of emerging markets. Over the past more than three decades the emerging market economies have opened up to global capital, technology, and mobility of people across the globe fundamentally changing their economic and business environments. Their gross domestic product (GDP) has been growing relatively faster than the global GDP and of the developed economies lifting millions of people out of extreme poverty. They have a burgeoning market of consumers particularly the middle classes. There is high demand for consumer products and services. There is an educated pool of people providing skills at relatively lower cost.

Despite the many redeeming features of emerging market economies, there are certain persistent problems that have been observed. Over the years, several of these emerging economies have faced financial crises. There is dearth of local talent and expertise to help run businesses effectively. Accessing finance and capital is difficult, and the cost of capital is often higher as compared to that in developed countries. Competition is not very intensive leading to weaker local companies that find it difficult to compete on the global level. Often, the government bureaucracies in these countries are inefficient and corrupt making it difficult to secure permissions and licenses to operate businesses. Even otherwise, corruption is endemic and foreign companies find it difficult to navigate the maze of regulatory mechanisms. They also face risks in evaluating the credentials of potential local business partners. The risks of operating are high leading to higher cost of operations. Contract enforcement is weak as judicial systems are inefficient. Customer credit is hard to access. Distribution of products and services poses stiff challenges as companies strive to lay down their network of supply lines. Such a long list of negatives can affect the prospects of emerging market economies preventing them from crossing the barrier of being emerging and ultimately becoming fully developed economies.

Starting with a few countries, the term emerging market has been expanding to cover a larger number of countries. There are several countries termed as emerging market economies depending on the criteria established by different institutions. Among the institutions that characterize economies as emerging are International Monetary Fund, Morgan Stanley Capital International, Dow Jones, and Standard and Poor's. There is agreement of considering these 15 countries as emerging economies: Brazil, Chile, China, Colombia, Hungary, Indonesia, India, Malaysia, Mexico, Peru, Philippines, Russia, South Africa, Thailand, and Turkey. Among these are the popular BRIC countries of Brazil, Russia, India, and China that are generally considered to be high on the ranking of emerging market economies. The list of emerging economies is subject to change as the parameters of the countries alter based on the criteria for considering a country as emerging market economy.

CSR and the Emerging Markets

Emerging market economies are seen as dynamic and growing in contrast to many developed economies that are viewed as stagnant and reaching the limits of their growth. Over the years, the focus of international business as well as commentators, analysts, and consultants has been shifting on the prospects of the emerging market economies.

The emerging market economies offer companies, both local and international, excellent opportunities. This leads to setting up manufacturing and service units in these economies. Rapid industrialization inevitably creates the problems of businesses encroaching upon the natural resources such as land, water, and air resources and livelihood of the indigenous population. The ideas of CSR and sustainability have taken roots in the developed nations due to long history of industrialization, stability in social, economic, and political conditions, the strength of legal systems, and well-established standards of business conduct. However, developing economies do not fare well on measures of CSR and sustainability.

They find themselves in a situation where they have to sacrifice considerations for the physical environment in favor of rapid industrialization. Often politicians and policy makers in developing economies put forth the logic that developed nations reached their present status of being developed through ignoring the physical environment so they, the developing economies, should not be subjected to unnecessary restrictions and asked to conform to stringent requirements that the developed nations never were required to follow.

The developing economies, particularly the emerging market economies, also believe that their nations are facing several problems such as poverty, deprivation, and social inequalities, corruption, and human rights violations. Besides, the emerging market economies face several other inherent problems such as unstable political conditions, irresponsible governance and profligate governments, and uncertainties related to foreign capital especially that invested in institutional investments such as equity markets. There are also the challenges of transition where rapid industrialization imposes social and political pressures that are hard to manage. The path from developing through emerging to developed economic status is strewn with many challenges and difficulties. In order to surmount these problems and deal with them, rapid industrialization and economic development is necessary. The emerging economies feel that they cannot be held back because of restrictive conditions of environmental protection and preservation.

The dilemma facing the emerging market economies of making a choice between rapid economic development at the cost of environment is a difficult one. There are trade-offs to be made. There are international regulations imposed by multilateral agencies such as the United Nations. There is a world economic order that is generally not favorable to the emerging economies. Their political and diplomatic clout is limited. Increasing interdependence between nations owing to the globalization and market reforms creates obligations that need to be fulfilled. In such a scenario,

the emerging market economies also need to be conscious of the social responsibilities of business. They have to conform to the global trends of having more corporate responsibility and accountability to the regulatory and other agencies. Overall, the emerging market economies have to walk a tightrope in managing the seemingly contradictory factors that they face.

CSR in the Emerging Markets

The focus of CSR has mostly been on the developed economies both in terms of theory and practice. CSR is established in developed country firms but it is becoming increasingly more important for firms in the developing countries especially in the emerging market economies. While much is known about CSR in developed countries, much less is known about the CSR practiced in the emerging market economies. However, three things are clear. First, the extent of adoption of CSR is higher in the developed countries as compared to that in developing countries. Second, the reason for the developing countries lagging behind their developed counterparts is their lower economic development. Third, CSR in developing economies may vary according to the specific conditions present in the countries and each emerging market may be unique and may also differ from the established CSR practices in developed nations. Such differences may be because of the cultural and value systems and the institutional environments in the emerging economies. Yet, there is a certain amount of diffusion of practices across the world mainly through the presence of multinational corporations that may direct and guide their local subsidiaries to adopt the CSR practices of their parent companies. Overall, the challenge, therefore, is to enable the developing nations turn into emerging e-economies and then graduate to being developed economies. Despite the lower economic development, CSR in emerging economies shows signs of dynamism and growth as well as adaptation through learning from the experiences of companies in developed economies.

It would be instructive as well as interesting to look at some specific emerging market economies in terms of their CSR profiles. A 2005 study of 127 listed companies on CSR in emerging markets, sponsored by the Organization for Economic Cooperation and Development (OECD), reveals that there is not much difference in the approaches to CSR between companies in the high-income OECD countries and the emerging market economies. Rather, there seems to be a surprisingly high level of comparability. Certain business sectors show relatively higher interest in CSR than others. Just as there is in the case of OECD countries, the emerging economies exhibit diversity in CSR policies and practices. CSR is a global phenomenon as evident in the case of several emerging economies and there is more formal engagement of companies in CSR activities. Despite being a global phenomenon, there are significant variations at the intra- and interregional levels. In several of the emerging market economies, CSR is a home-grown phenomenon rather than imitated or imposed from outside. The drivers of CSR in emerging market companies seem to be similar to those in the developed countries. Such drivers are measures to attract and retain employees, to improve market positioning, and to protect reputation (Baskin and Gordon 2005).

KPMG reports on CSR in South Africa suggest that South African companies do very well on CSR reporting but less enthusiastic on environmental matters. As evidence of context-specific CSR, the South African companies report on how they deal with AIDS among their employees and the setting of whistle-blowing hotlines for reporting corruption.

India has a long tradition of philanthropic and community programs. In recent years, corporate philanthropy is shifting toward corporate social investment. There is a growing trend toward reporting on CSR and sustainability in which the companies report their environmental impact. Another example of an emerging economy is that of Malaysia where the emergence of CSR is closely linked to the country's Vision 2020 development plan that emphasizes the government's policy to enhance standards of corporate governance and business ethics.

Summary

CSR operates on the principle of reciprocity between businesses and society. Both receive and give to each other in terms of resources and products and services. The term corporate social responsibility has been defined in various ways by different experts yet there is no unanimity in its meaning and interpretation. Generally, CSR is viewed as a balance between social, economic, and environmental imperatives that are also termed as the triple bottom lines. Although a new term, CSR has been practiced since long in its traditional forms such as philanthropy, charity giving, and community development. CSR is a global trend now and popular around the world.

Emerging market or emerging market economies are those developing countries that have grown faster than other developing countries in recent years. They also have some redeeming features such as large markets, educated populace, supporting government policies, and a desire to develop fast economically. They also face challenges of inept and corrupt governments, social and political pressures that resist change, and lack of access to high technology, expertise, and capital.

CSR poses a dilemma for the emerging market economies as it is viewed as restraining and limiting to the rapid industrialization that such economies seek. CSR imposes responsibilities on businesses that constrain their growth or prevent them from achieving their full potential. These economies also feel unfair treatment as the developed nations have achieved economic development at the cost of environment while the emerging trend is to place more emphasis on environmental protection and preservation. The emerging economies desire to get through the stage of developing through fast economic growth that leads to challenges of affecting sustainability adversely.

The adoption of CSR in emerging market economies lags behind that in developed nations. But they are fast catching up the global trends. There is wide variation in the practices of CSR in the emerging economies. Some of the

practices are global and common across countries but there are certain CSR practices that are specific to the context of a particular emerging economy.

Definition

Corporate social responsibility in tourism refers to the social responsibilities of tourism companies (economic, legal, ethical and discretionary expectations of a society) (Peters 2016).

Today's global tourism industry is of high economic importance (United Nations World Tourism Organization 2020; World Travel & Tourism Council 2019). On one hand, it has strong economic, environmental, and social impacts while at the same time relying on open healthy natural resources, a constructive social operating climate, and a positive economic environment. The tourism industry therefore needs to design tourism in a way that it shows positive values for societies and businesses at the same time. This can only be successful if companies are prepared to take social responsibility for their actions as well as planning those responsibilities to generate a competitive advantage (Fifka 2017a, b). Accordingly, corporate social responsibility (CSR) is a vital component of the tourism industry.

This chapter will start by discussing the challenge of defining CSR. This provides a baseline to explain the importance of CSR within the tourism industry. Of particular significance are thereby the four dimensions of CSR: community relations, employee relations, environmental issues, and product quality.

The last five decades have witnessed phenomenal growth and interest in corporate social responsibility (CSR) across different industrial sectors involving multinational corporations as well as small- and medium-scale enterprises (SMEs) in developed and developing countries. It is linked with increasing firm investments in CSR planning and implementation (Palacios-Marqués and Devece-Carañana 2013). However, CSR is a contested concept and hence lacks a universally accepted definition. The World Business Council for Sustainable Development (1999) defines CSR as the continuous commitment by business through behaving ethically in their trade and contributing to economic development and at the same time improving the quality of life of the workforce, their families, local community, and society at large. This implies that CSR is not a business event or activity but a main preoccupation of businesses which appears to be much of a strategic decision (Fernandez-Kranz and Santalo 2010) aimed at societal good beyond legal and industry obligations (Torelli et al. 2012). Social responsibility of businesses encompasses the economic, legal, ethical, and discretionary expectations that society has of organizations at a given point in time (Carroll 1979, p. 500). A CSR commitment signifies a firms' acceptance to pursue and fulfill obligations that benefit societies and stakeholders in their value chain (McLachlan and Binns 2014). Kucukusta et al. (2013) conceptualized CSR as an organization's willingness to acknowledge and implement sociocultural and environmental obligations aside from their commercial duties. Accordingly, corporate social responsibility in tourism refers to the social responsibilities of tourism companies (economic, legal, ethical, and discretionary expectations of a society) (Peters 2016).

The increasing attention to CSR in business operations coincided with the exponential growth

in global tourism in the 1950s, where there were only 25 million international tourist arrivals to the reported 1.5 billion international tourist arrivals at the end of 2019 (United Nations World Tourism Organization 2020). The resultant mass tourism has exerted considerable pressure on diverse environmental and sociocultural resources and communities leading to adverse effects including noise pollution, water pollution, destruction of vegetation, congestion, despoliation of the environment, crime, and violence (Liu and Var 1986; Long et al. 1990; Milne 1990; Gursoy and Rutherford 2004). Recognition of the potentially devastating consequences of mass tourism in the 1960s led to the growth of concerns for visitor management in the 1970s and the birth of the green or alternative concept of tourism in the 1980s with the consequent growth of sustainable tourism in the 1990s (Swarbrooke 1999). Sustainable tourism was adopted to address implications of tourism for visitor need, environment, host community, and other industries (World Tourism Organization; WTO 2015). More recently, empirical evidence has linked tourism to climate change following increasing carbon dioxide emissions attributable to the consistent growth in tourism, in particular international tourism (De Vita et al. 2015; Kalayci and Koksall 2015; Zaman et al. 2016).

The need to adopt CSR in tourism became more pressing following the UN's Earth Summit of 1992 held in Rio de Janeiro, where actions to protect the environment were given utmost attention (United Nations Conference on Environment and Development 1992). The Summit sought to align global economic development agenda with the conservation of the environment (Agenda21). The emerging treaty enjoined countries to preserve tropical rainforest and endangered animal and plant species and reduce pollution and climate change through a reduction in the emission of carbon dioxide and other greenhouse gases as well as the cleaning and conservation of the environment (atmosphere, climate, landforms, hydrosphere, and oceans). It also pressured businesses to adopt a more proactive role in protecting the natural and social environment in its operating countries. For tourism this could even be argued

that the above outlined contextual circumstances make CSR implementation imperative. CSR in tourism and hospitality aims to protect the tourism resources found in the social, cultural, and the physical environment (Kasim 2006), both as attraction and for the host community.

The implementation of CSR in tourism is also in line with the regulations of the UNWTO, World Travel and Tourism Council, and the Green Hotels Association (Tsai et al. 2012). The UNWTO (2018) describes CSR as the tourism firms' extra-legal and extra-economical behavior to strengthen the business case of being a good business. Given the heterogeneity of firms involved, CSR activities in tourism are multifaceted. However, CSR strategies in tourism are categorized into four dimensions: community relations, employee relations, environmental issues, and product quality (Holcomb et al. 2007; Levy and Park 2011).

Community relation activities entail firm support is provided to communities through the implementation of charitable giving, educational initiatives, and volunteer programs. Furthermore, community relation CSR strategies also include monetary donations to support community activities and education, campaigns, and ventures that promote the welfare of the community, the assistance provided to communities to resolve the challenges faced, and the support for social issues (Boccalandro 2009; Tamajón and Aulet 2013; Turker 2009). CSR of community relations is contextualized and localized to resolve problems that directly affect a specific cultural group, considering their beliefs and values (Kang et al. 2016; Luo et al. 2019). To maintain community relations, tourism firms could, for example, use CSR to regulate tourists' influx through visitor sensitization campaigns (Karlsson and Dolnicar 2015; Appiah 2019) to ensure that tourist behavior conforms to that of the community, thereby maintaining a positive relationship.

Community CSR activities are necessary because tourism firms are often perceived as exploitive (Young 2006), linked to social vices, increase immorality and crime (Youn et al. 2018; Luo et al. 2019) and breakdown of ties in families and societies. These perceived immoral impacts on residents and patrons, especially the youths,

are felt severely by the host community leading to an occasional antagonistic attitude toward tourism development. CSR in tourism reduces these negative social perceptions and increases the acceptance of tourism business in existing communities, which also opens avenues for investment in other communities. The residents of host communities, on the other hand, are receptive to tourists when tourism firms implement CSR with social benefits to its members.

CSR employee relation strategies are about a company's level of involvement in employee-related issues, such as ensuring employees' health and safety, the provision of retirement benefits, favorable union relations, the safeguarding of health and safety in the workplace, employee training, the possibility of employee fringe benefits, and the provision of recreational activities (Paek et al. 2013). Other employee relation activities include showing concern for retired employees by allowing such retirees to transfer their medical insurance without underwriting (Kucukusta et al. 2013). As a labor-intensive industry, employee relation CSR is crucial in tourism, as it has implications for employee performance. According to Supanti et al. (2015), employees are a major stakeholder to CSR in tourism as they produce and deliver services to tourists. Studies have shown that tourism and hospitality employees of firms that implement CSR are more satisfied and committed (Youn et al. 2018; Appiah 2019) and are willing to put in more effort to drive corporate success (Islam et al. 2016). Potential and existing employees' sought to be associated with firms that implement CSR inwardly in the form of ensuring occupational safety and designing decent tasks (Hornig et al. 2018) and outwardly in the form of community and environmental support. In the future, this will gain further importance because of expected labor shortages.

Employees in the hospitality industry especially the housekeeping division are prone to hazards at work, and, as a 24/7 industry, employees work during all hours of the days of the week that can lead to a variety of work-family conflicts. CSR in tourism is therefore extended to include employees and their families

(Farrington et al. 2017) to reduce work-family conflicts associated with working in the tourism industry. This has become a human resource issue as job applicants choose hospitality firms to work in based on their CSR (Quinn 2013). Tourism firms through social relations uphold moral values of host communities through supporting the education of members of the community, providing skills training for the youth, and celebrating the local culture through staged events. In tourism, it is necessary for firms to undertake CSR in the areas of hiring members of the local community, paying high wages to local employees to increase income generation, employing women, and having women's presence in top management (Polonsky et al. 2013; de Grosbois 2015; Kang et al. 2016; Islam et al. 2016).

Tourism entails movement within local environments (**environmental issues**) to consume sociocultural features with a high risk huge for negative effects (Karlsson and Dolnicar 2015; Chi et al. 2019). Consequently, CSR strategies of tourism firms are dominated by environmental activities because consumers most value corporate efforts that are easily recognized and tangible to their destination experience (Levy and Duverger 2010). Furthermore, environmental activities aimed at mitigating the negative environmental and social impacts of tourism, are sometimes related to a reduction in operational cost thereby making such CSR activities appealing to tourism and hospitality firms (Kucukusta et al. 2013) aimed at mitigating the negative environmental impacts of tourism and supporting and sustaining the environments, society, and cultures consumed by tourists. CSR serves as a balance between the consumptive and preservative characteristics of tourism (Telfer and Sharpley 2008). A set of environmental practices of tourism firms is best described as "recycle, reduce, reuse, and replace." For instance, hotels often recycle a number of materials such as glass and paper, establish guidelines to reduce the use of resources and energy, reduce the use of packaging for food items, and remind guests and employees to switch off electrical appliances when not in use (Kucukusta et al. 2013). Tourism firms have been noted to exhibit resource-efficient practices such as employing

linen and towel reuse programs and installing energy-efficient appliances and low water flow fixtures (Levy and Park 2011). In addition, environmental CSR activities are evident in tourism firms through green/eco-certifications and the introduction and use of labels such as green and eco (Calveras 2015; Karlsson and Dolnicar 2015). Words of green, sustainable, and eco and alternative forms of mass tourism are associated with CSR in tourism and hospitality (Sheldon and Park 2011; McLachlan and Binns 2014; Supanti et al. 2015).

Even so, in particular, hotels and restaurants have been criticized for high consumption of water, energy, and nonreusable materials and generation of waste and environmental pollution (Kang et al. 2015; Youn et al. 2015; Farrington et al. 2017; Ghaderi et al. 2019). In relation to airlines, the proportion of carbon emission from airlines attributed to tourist movement is forecasted to rise (Cohen et al. 2014; Feng and Tseng 2017) relative to increasing international tourism contributing to human-induced climate change, therefore warranting CSR-action.

Other areas of potential for CSR activities are protected zones, where tourists sometimes have destroyed ecological lives through overcrowding and overuse of the physical environment. Accordingly, environmental CSR should be adopted in tourism to reduce climate change (Park and Levy 2014; Feng and Tseng 2017) and pollution and manage both the tourists and the physical environment. Tourism firms engage in this form of CSR by adopting ecologically friendly behavior of appropriate waste management, recycling, and using engines that emit fewer emissions among others.

However, CSR in the environment in terms of activity, frequency, and the amount of resource commitment is influenced by the impacts of tourism in a particular environment (Chi et al. 2019). Thus, tourism firms with perceived positive impacts are less likely to get involved in CSR, while those with high perceived negative environmental impacts would adopt CSR to reduce adverse effects. Closely related to this is the issue of resource dependence where tourism managers that depend on the natural resources or host

community's culture are inclined to socially responsible behaviors with a higher willingness to support and pursue programs to protect the environment (Chi et al. 2019) since these resources are the core of their business without which their existences are threatened. The tourism resources are the environment, and its protection translates into the preservation of resources.

The fourth dimension is **product quality**, where CSR is directed to improving the quality of goods and services offered to tourists. Tourists are known to have a preference for clean and quality environments with low levels of pollution, and hence tourism businesses are flourishing under such conditions. This includes issues of fulfilling international standards for safe drinking water, quality air, good roads, and safe food to attract tourists (Farrington et al. 2017), because customers are key to every business. Thus, CSR targeted at products (Ghaderi et al. 2019) will translate into increased sales as consumers seek quality products (Lee 2008).

Besides the foregoing CSR strategies, the UNWTO (2015) additionally identified important CSR fields in the areas of supplier relations, customer services, stakeholder involvement, and business operations (UNWTO 2010; International Trade Centre and World Tourism Organization 2015):

- CSR in **supplier relations** includes green and responsible purchases, protecting local suppliers and enhancing their prosperity, anti-corruption measurements, and avoidance of money laundering activities as well as supplier involvement in corporate decisions.
- **Customer service CSR** aims to ensure customer security and health and non-discrimination behavior in services delivered to clientele.
- CSR to enhance **stakeholder involvement** entails providing customer, staff, and host community with information and relationship management program to ensure appropriate participation.
- CSR of **business operations** includes certifications to show commitment and provide evidence for the adherence to norms, standards,

and eco-design as well as securing the professional development of staff through training and partnerships for education, a diversity management strategy, security and health services for all employees, the creation of wealth and its complementary benefits, anti-corruption measurements, and the avoidance of money laundering.

The goodwill of organizations through CSR benefits stakeholders, it provides increased profits for investors, higher dividends for shareholders, a quality product for consumers, more satisfied employees, and a better protection of the host community. Moreover, the adoption of sustainable business models (Calveras 2015) reduces material use, waste generated, and the amount of money spent on waste management.

Overall, the inclusion of CSR measurements in the strategic goals of tourism businesses has a number of positive impacts. For example, hotels that practice CSR perform well (Ghaderi et al. 2019) through a cordial relationship with their customers, employees, and the host community. Additionally, CSR programs in tourism operations sustain and restore a positive image and reputation (Graci and Kuehnel 2010; Han and Yoon 2015; Islam et al. 2016) of implementing firms. Other benefits of CSR are better financial performance (Lee and Park 2009; Kang et al. 2010; McLachlan and Binns 2014), the attraction of more customers (Lee and Shin 2010; McLachlan and Binns 2014; Luo et al. 2019), gaining a competitive marketing edge over competitors and substitutes (Farrington et al. 2017) through the enhanced image (McLachlan and Binns 2014), a higher self-respect for the firms' manager (Chi et al. 2019), and improved work attitudes of employees (Youn et al. 2018).

A strong factor influencing CSR measurements in tourism businesses is the size of the business. Firms with large customer bases and coverage effectively implement CSR (Ghaderi et al. 2019; Youn et al. 2015; Tamajon and Font 2013; Amponsah and Dartey-Baah 2011), while small- to medium-scale tourism firms assume a passive role of reacting to criticism of not

implementing CSR through occasional CSR activities (Baniya et al. 2019).

Even more, the implementation of CSR in tourism is faced with a variety of additional challenges. One of which is making all stakeholders, especially consumers, aware of CSR activities as a lack of awareness is synonymous with a perception to not implementing CSR (Shen et al. 2015; Luo 2018), rendering its role as a marketing tool ineffective. Tourism firms therefore have to adopt strategies of making their CSR known to stakeholders.

Summary

The global tourism industry creates a number of economic, social and environmental issues, while at the same time relying open healthy natural resources, a constructive social operating climate and a positive economic environment. To be successful, its operations need to be designed in a way that shows its positive values for societies and businesses. However, this can only be effective if companies are prepared to take social responsibility for their actions as well as planning those responsibilities to generate a competitive advantage. Accordingly, corporate social responsibility (CSR) is a vital component of the tourism industry. Consequently, CSR measurements should be included in the strategic goals of tourism businesses. As CSR programs in tourism operations sustain and restore a positive image and reputation, they lead to a better financial performance, attract more customers, help to gain a competitive marketing edge, facilitate a higher selfrespect for firm's manager and helps to improve work attitudes of employees. Yet, despite a variety of challenges, tourism firms have to adopt strategies of making their CSR known to stakeholders to be successful in such a competitive market.

Definition

The “CSR pyramid” by Archie B. Carroll is probably the most widespread and best-known model of CSR in the scholarly literature (see, e.g., Visser 2006, p. 33; Verfürth 2016, p. 32). It depicts a pyramid divided into four levels, which represent four kinds of responsibilities (economic, legal, ethical, and philanthropic), that organizations, especially companies, hold toward their stakeholders and society at large. Together, these four responsibilities constitute “total CSR” as Carroll calls it (Carroll 1991, p. 40).

Introduction

The famous CSR pyramid, published by Archie B. Carroll, shows four layers of responsibility in a hierarchical arrangement: an economic, legal, ethical, and philanthropic responsibility. The article in which the model was published for the first time still ranks as one of the most frequently downloaded articles from *Business Horizons* in the last 90 days (Elsevier Journals 2019). Accordingly, the CSR pyramid has significantly shaped the international perception of corporate social responsibility (Scherer and Patzer 2011, p. 322).

The Precursor Model

The preparatory work for the model dates back to 1979, when Carroll published his article “A Three-Dimensional Conceptual Model of Corporate Social Performance” (Carroll 1979). In this article, he offers a conceptual model that comprehensively describes essential aspects of corporate social performance (CSP). It aims to answer three major questions of concern for academics and managers alike:

1. What is included in corporate social responsibility?
2. What are the social issues the organization must address?
3. What is the organization’s philosophy or mode of social responsiveness? (Carroll 1979, p. 497)

In response to the first question “What is included in CSR?,” Carroll presents a four-part definition that addresses the entire range of obligations business has toward society. He states that companies have these four responsibilities:

- Economic responsibilities
- Legal responsibilities
- Ethical responsibilities
- Discretionary responsibilities (Carroll 1979, p. 499)

The graphical model he uses to illustrate these four categories displays a column consisting of four building blocks. The first and largest building block is at the base of the column and is called “economic responsibilities,” and the second largest is “legal responsibilities,” followed by “ethical,” and, finally, the smallest is “discretionary responsibilities” (later referred to as “philanthropic,” Carroll 1991). By choosing different proportions, Carroll suggests the relative magnitude of each responsibility. All four categories are not mutually exclusive nor are they supposed to represent a continuum with economic concerns on the one hand and social concerns on the other hand. The categories are not cumulative nor additive but are listed in the order of their assumed foundational importance and role and shall offer a classification scheme for the different kinds of social responsibilities business has (Carroll 1979, pp. 499–500).

In accordance with this four-part column model, Carroll then articulates a definition of CSR, which is based on societal expectations:

“The social responsibility of business encompasses the economic, legal, ethical, and discretionary expectations that society has of organizations at a given point of time”. (Carroll 1979, p. 500)

Mark Schwartz has emphasized how Carroll’s four categories or domains of CSR have been used by numerous theorists in their development of more comprehensive CSR models or frameworks (Schwartz 2011). And two prominent business and society scholars, Wood and Jones, have observed that Carroll’s four CSR categories have “enjoyed wide popularity among Social Issues in

Management (SIM) scholars” (Wooda and Jones 1996, p. 45). Schwartz goes on to conclude that such use, as well as its acceptance and impact, suggests that Carroll’s CSR categories/domains, as well as his CSR pyramid, remain a leading paradigm of CSR in the SIM field (Schwartz 2011, p. 88).

With regard to the second question, Carroll strives to identify the “social issues” to which his conceptual framework for CSP can be applied. Carroll notes that issues change over time and differ from industry to industry. He further argues that there is no consensus on which social issues should be addressed precisely. Therefore, identifying social issues is an important aspect of CSP analysis. In later writings, he referred to these social issues as stakeholder issues. Turning to the third question, Carroll deals with the term “social responsiveness” as referring to the philosophy, mode, or strategy behind business’s managerial responses toward expectations of society and social issues. Response categories range from giving no response (doing nothing) to responding proactively (doing much) (Carroll 1979, p. 501). Finally, Carroll integrates all three aspects, i.e., the definition of social responsibility of business illustrated by the column model, the need for identifying social issues, and the degree of social responsiveness, into one three-dimensional, cube-like “corporate social performance model” (Carroll 1979, p. 503).

According to Max Clarkson, the development of Carroll’s three-dimensional model represented a new conceptualization of CSP. Clarkson was the first to refer to it as “Carroll’s cube” (Clarkson 1995, 245). He called it comprehensive and integrative and asserted that the “strength of its influence can best be judged by its longevity and that of its progeny” (Clarkson 1995, p. 245).

Carroll proposed that this three-dimensional CSP model might help managers to conceptualize key issues needing to be addressed in social performance, to categorize thinking about social issues, and to enhance planning and diagnosis in social performance. For academics, the CSP model intends to help to clarify and integrate various definitional strands (Carroll 1979, p. 504).

Description of the CSR Pyramid

In 1991, Carroll, drawing on his earlier work from 1979, developed his famous pyramidal model, which embraces the entire range of business responsibilities and is termed “the pyramid of corporate social responsibility” (Carroll 1991). The CSR pyramid extracted the basic definition of CSR from his CSP model and focused on developing it further. In 2014, researcher Jeremy Moon termed Carroll’s CSR pyramid one of the most “famous” and “influential” frameworks for studying the management of CSR (Moon 2014, pp. 20–21).

As in 1979, Carroll distinguishes four different categories of responsibility – economic, legal, ethical, and philanthropic – which together constitute “total” CSR.

The pyramid’s lowest layer, understood, thus, as the foundation of CSR, is the economic responsibility: Being a profitable company that provides society with goods and services is, according to this model, the basic prerequisite for all other levels of responsibility. Moon argues that a strength of the CSR pyramid is that it is founded on economic responsibility, and this reminds us that CSR extends to the core business (Moon 2014, p. 21). Like Milton Friedman (Friedman 1970), Carroll highlights the economically motivated, i.e., profit-oriented, production of goods and services as the fundamental responsibility of a company. Companies were given the sanction to provide society with goods, services, and jobs, and profit is the incentive or reward they were given. He argues further that the idea of a profit motive was transformed into a maximum profit motive at some point, and this is still a dominant mindset of many business people, even today. Also in line with Friedman, he offers some considerations that characterize a company’s economic responsibility, e.g., that it is important to perform in a manner consistent with maximizing earnings per share and to be committed to being as profitable as possible (Carroll 1991, pp. 40–41).

In the CSR pyramid, economic responsibility is reflecting the historical development as seen by Carroll, followed by the aspect of legal responsibility: Companies should not only operate

according to a legitimate profit motive but are also expected to comply with applicable laws. Laws and regulations are seen as “codified ethics” because they are based on notions of fair operations. Today, both economic and legal responsibilities should be seen as coexisting fundamental concepts of free-market economies. Legal responsibilities are further characterized, e.g., by the importance to perform in a manner consistent with the existing law and to comply with federal, state, and local regulations (Carroll 1991, pp. 40–41). In short, economic and legal responsibilities are “required” by society as conditions for operating and staying in business.

The third layer represents ethical responsibilities. In contrast to “codified ethics,” ethical responsibilities compel companies to behave in accordance with socially expected and ethically legitimized standards, norms, values, or expectations that have not been codified into law (yet). Carroll draws attention to the interdependence between the second and third layer of his model. On the one hand, changing ethics might precede new regulations and laws; on the other hand, the third layer shows that society has even higher expectations on managers to operate at levels above those required by law. Statements that help to characterize ethical responsibilities are, for example, that it is important to perform in a manner consistent with expectations of societal mores and ethical norms and recognize and respect new moral orientations adopted by society (Carroll 1991, p. 41). Whereas economic and legal responsibilities are “required” by society, ethical responsibilities are “expected” by society.

The top level of the pyramid is composed of “philanthropic responsibilities.” Unlike the first three responsibilities, this one is not directly related to how companies act in pursuing their goals but stands for what companies are willing to do voluntarily for the benefit of society or community, such as business contributions of financial or human resources for charitable purposes and community engagement. Philanthropic responsibilities can be distinguished from ethical responsibilities in that they are purely discretionary, i.e., there is no obligation based on an ethical principle or value demanding it. The society

expects companies to assume their ethical responsibilities, but if companies do not engage in activities or programs for promoting human welfare, they are not seen as behaving in an unethical manner. Therefore, philanthropy might be highly “desired” by society but is still not seen as required as the three other layers of the pyramid. Statements that summarize philanthropic components of CSR are, e.g., to perform in a manner consistent with the expectations of society in terms of charity or to assist the fine and performing arts (Carroll 1991, pp. 41–42). Carroll argued that the philanthropic responsibilities are often thought of in the category of businesses desiring to be good corporate citizens.

All four layers of the CSR pyramid constitute “total CSR” and, in terms of management, must be addressed simultaneously (Carroll 1991, p. 43). It is here that Carroll’s model significantly differs from the work of Friedman (1970). The first three layers more or less correspond to Friedman’s understanding of responsible management, which is “to make as much money as possible while conforming to the basic rules of society, both those embodied in the law and those embodied in ethical custom” (Friedman 1970). Friedman, however, emphasizes the economic responsibility and does not say much about legal and ethical responsibilities other than to mention them. He criticizes philanthropy – which, in his article, he actually treats as a synonym for social responsibility – as illegitimate in a corporate context because managers should be the agents of stockholders in the first place and thus be obliged to maximize profit instead of diminishing it by donating for “social purposes.” Carroll, by contrast, states that engaging in philanthropic activities goes hand in hand with “enlightened self-interest” of business as “good corporate citizens” (Carroll 1991, p. 43).

Carroll’s model serves as a framework to understand a company’s responsibilities as “required, expected, or desired” by society. These responsibilities, of course, may vary in magnitude because of company size, industry, philosophy, corporate strategy, etc. Nonetheless, to be socially responsible, all companies should strive to “be profitable, obey the law, be ethical

and, be a good corporate citizen” (Carroll 1991, p. 48). For these purposes, managers need to reconcile their objectives with those of their stakeholders. This is achieved by stakeholder management, i.e., describing, understanding, analyzing, and managing stakeholders and their interests (Carroll 1991, p. 43). He argues that five questions need to be addressed in order to achieve comprehensive stakeholder management:

1. Who are our stakeholders?
2. What are their stakes?
3. What opportunities and challenges are presented by our stakeholders?
4. What corporate social responsibilities (economic, legal, ethical, and philanthropic) do we have to our stakeholders?
5. What strategies, actions, or decisions should we take to best deal with these responsibilities? (Carroll 1991, p. 44)

In order to answer question no. 4, Carroll offers a stakeholder/responsibility matrix that helps managers to organize their thoughts. It shows the four types of responsibilities (economic, legal, ethical, and philanthropic) on the vertical axis of the matrix, in reflection to a listing of the important stakeholders of the company on the horizontal axis of the matrix. By analyzing the four types of responsibilities for each stakeholder, companies may maintain an analytical database to support their stakeholder management and, ultimately, decision-making. Carroll draws special attention to the linkage of ethical responsibility (third layer of his CSR pyramid) and major stakeholder groups. He distinguishes three types of management (immoral, amoral, and moral), which he previously defined in his article “In Search of the Moral Manager” (1987). Based on these three moral types, he outlines possible orientations toward five major stakeholder groups (owners, employees, customers, local communities, and the society at large). Carroll aims to gain a more comprehensive understanding of what it means to manage morally – his favored and recommended option of the three types of management morality – and of what this implies for interacting with stakeholders (Carroll 1991, pp. 46–47). Because it is intuitive in nature, Carroll’s CSR pyramid ranks high in popularity and acceptance in the CSR discussion (Mildenberger et al. 2007, p. 13).

CSR Pyramid, Fig. 1 The pyramid of corporate social responsibility (Carroll 1991, p. 42, Fig. 3)

Jeremy Moon argues that its simplicity is one of its major strengths (Moon, 21) (Fig. 1).

Criticism and Issues

As Carroll himself says, “no metaphor is perfect, and the CSR pyramid is no exception” (Carroll 1991, p. 42). The model has been criticized especially because of its hierarchical structure, even though Carroll himself states that all four layers are in constant and dynamic tension with one another. According to Visser, it is not fully clear why Carroll portrays the four different responsibilities as a hierarchy (Visser 2006, p. 43). Mildenberger/Khare/Thiede suggest that the hierarchical pyramidal form was chosen as a common method of presentation in economy and more or less reflects the relevance of the four responsibilities as perceived by managers (Mildenberger et al. 2007, p. 13). Carroll has argued that the sequence, with economic as the base, is foundational to the conduct of business and that economic sustainability is essential for the other

responsibilities to be relevant. If companies are not economically profitable and sustainable, the other responsibilities become less relevant. Carroll later confirms this hypothesis with empirical studies of the four responsibilities. The first study, published in 1985, showed that experts were capable of distinguishing among the four responsibilities. In addition, a conducted factor analysis ascertained that there are four empirically interrelated but conceptually independent components of corporate social responsibility. The weighting of the four layers within the model reflects the importance that 241 surveyed executives rate it (Aupperle et al. 1985). Another study, which measures the weighting of the four responsibilities by European managers, was published in 1996 (Pinkston and Carroll 1996) and later supported by the study of Edmondson/Carroll in 1999 (Edmondson and Carroll 1999).

Another point of criticism concerns the applicability of the CSR pyramid in different localities and in different organizational contexts. Visser argues that the pyramid is based on research in a US-American context. He goes on to say that in

developing countries, the order of the CSR pyramid would probably differ from Carroll's model: the economic responsibilities would still be given highest priority, followed by philanthropy and legal and ethical responsibility (Visser 2011, pp. 488–489). Also, Crane and Matten argue that although it is possible to apply Carroll's pyramid in Europe, there are certain differences, and the interdependencies of the layers would be different from those described by Carroll (Crane and Matten 2007).

Carroll had given thought to the applicability of the pyramid in the global context when in 2004 he set forth his pyramid of *global* corporate social responsibility and performance. Though he did not suggest a reordering of the four CSR categories, he suggested that the CSR pyramid could be used as a base point or framework for studying its applicability in diverse locales (Carroll 2004). It was implicit in this article that he was speaking of its applicability in developed economies. Its applicability in less developed countries or emerging economies was not addressed. Interestingly, however, many articles, dissertations, and theses are appearing on the scene today in which the CSR pyramid is being used as a foundational reference point for studying CSR in developing economies.

In addition to the criticism mentioned by Visser, the model does not comprise new emerging forms of companies, such as “social businesses,” as described, for instance, by Yunus and Weber (2010). These social enterprises' objective is to address social problems while being financially self-sustainable but not being as profitable as possible (see statement no. 2, Carroll 1991, p. 40). These new forms of businesses reinvest profits in the business itself in order to increase positive social impacts. For the most part, these innovative business forms (e.g., social enterprises, B-corps) began appearing years after the CSR pyramid was articulated. Further, the general public may look at these companies differently than they do CSR among mainstream companies. In later writings, Carroll distinguished the rise of CSR exemplar firms to include social entrepreneurship and B-Corps and leading CSR performers from what he termed “mainstream

adopters,” firms that did not have specific social agendas emanating from their initial formations. These mainstream adopters include conventional businesses that have adopted, practiced, and achieved various degrees of CSR excellence but did not have an initial social purpose (Carroll et al. 2018, p. 43).

Carroll's Pyramid of CSR: Taking Another Look

Partly in response to emerging questions, misinterpretations of the model, and criticisms, Carroll published a review article, in which he takes another look at his pyramid of CSR in order to discuss some aspects of the model that were not clarified when it was initially published. He once more emphasizes that the four responsibilities shall help to delineate in some detail a company's responsibility toward society (Carroll 2016, p. 2). He further points out that ethics permeates and saturates the pyramid and, thus, should be seen as a factor that is present in all of its layers. For example, in the economic responsibility category, the pyramid implicitly assumes a free enterprise society in which capitalism is seen as a legitimate, fair, and just system. In the legal responsibility, it is noted that most laws and regulations were initially created based upon ethical precepts. In the ethical responsibility category, ethics stands on its own, and in the philanthropic responsibility, business giving is sometimes ethically motivated by firms striving to do the right thing, whereas other firms may just be trying to enhance their reputations (Carroll 2016, p. 5). In short, the ethics dimension might be seen as cutting through and permeating all four categories of the pyramid.

Carroll describes that here are tensions and trade-offs when a company seeks to follow all four responsibilities (e.g., especially with regard to short-term and long-term profitability). But tensions and trade-offs are important decision points, and the layers of the pyramid do not necessarily have to be in complete opposition to one another (Carroll 2016, p. 8). The CSR pyramid should always be viewed in its entirety and not be

reduced to a stack of single responsibility layers. Carroll desires his pyramid to be understood as a “sustainable stakeholder framework” and one that is seen as an “integrated, unified whole” (Carroll 2016, p. 6). Its four components address different stakeholders with reference to the varying priorities in which stakeholders might be affected. In addition, the pyramid should be seen as a dynamic, adaptable framework that overarches into future generations and, therefore, can be called sustainable itself. According to Carroll, “A consideration of stakeholders and sustainability, today, is inseparable from CSR” (Carroll 2016, p. 6). Finally, Carroll again addresses the global applicability of his CSR pyramid within different geographical localities and different organizational contexts and suggests that future research will further explore these topics. Carroll concludes by saying that CSR, the pyramid of CSR, and related models and concepts face an optimistic future and are on a rising trajectory (Carroll 2016, p. 7).

Summary

The CSR pyramid is, according to Carroll himself, a model that constitutes “total CSR.” It depicts a triangle divided into four layers in a hierarchical arrangement, which represent four kinds of responsibilities (economic, legal, ethical, and philanthropic). Organizations, especially companies, should follow all four responsibilities hold toward their stakeholders and society at large (Carroll 1991, p. 40). There has been a lot of criticism and misinterpretations of the model especially with regard to the hierarchy of responsibilities, but still it is one of the most widespread and best-known models of CSR (see, e.g., Visser 2006, p. 33; Verfürth 2016, p. 32).

Definition

When talking about the definition, there is no exact agreement on what corporate social responsibility (CSR) means. There are various definitions that take into account various dimensions. Andersen 2003 in (Dahlsrud 2006), defined CSR as the companies' interests with the emphasis on nature or environment for the future generation. Some claim the importance of identifying the stakeholders as they see CSR as the "obligations or duties of an organization to a specific system of stakeholders." Meanwhile, Lu et al. (2019) describe CSR as the responsibilities of companies on their vision and mission and also responsibility for the impacts on society. From these various approaches, in general CSR can be defined as a company's effort to contribute to sustainable development, which is denoted as development that meets existing generation's needs without endangering future generations' ability to meet their own needs and focuses on how to obtain the integration of economic, environmental, and social stringent requirements (Kim et al. 2014). To hold the companies accountable for their commitment on social responsibility, the framework for CSR reporting has evolved. Companies' activities that indicate the incorporation of economic, social, and environmental issues in their business activities and interactions with stakeholders are called CSR reporting. Nonfinancial information on a company's interactions with various stakeholders, as well as its physical and social surroundings, is included in CSR reporting (Orzel 2020).

CSR Report Quality

Introduction

Civilization has evolved in the process of globalization, and this caused people's awareness on their existence to change which led them to have redefined expectations toward environment and affected their expectations regarding the role, function, and responsibilities of companies. To meet these new expectations, the term corporate social responsibility (CSR) was founded.

There is no exact agreement on the definition of CSR, but various definitions of CSR in management and organizational literatures have emerged for the last two decades. There are several approaches that are used to try to establish the definition of CSR which involves several dimensions such as economic, environmental, social, stakeholders, and voluntariness. For example, CSR is described by the World Business Council for Sustainable Development (WBCSD) as a commitment of corporations to contribute to sustainable economic development by working with employees, their families, the local community, and society as a whole to improve citizens' quality of life (Inyang et al. 2011). Meanwhile, the European Communities Commission takes a more commonly proposed approach to CSR, defining it as a concept in which corporations choose to contribute willingly to a better community and a cleaner environment. According to some academics, CSR refers to a company's overall relationship with all of its stakeholders (Tokoro 2007).

According to these definitions, CSR can be defined as a company's efforts to promote sustainable development, which means development that meets the needs of the current generation without jeopardizing the ability of future generations to meet their own needs and concentrates on how to achieve the integration of economic, environmental, and social stringent requirements (Kim et al. 2014). CSR encompasses a wide range of societal duties that should be fulfilled by corporations that operate within those societies. Specifically, CSR requires a company to identify its stakeholders and consider their needs, goals, and values in day-to-day decision-making.

Several institutions have attempted a strategy to get the commitment of corporations regarding social responsibility. In the 1960s, the Netherlands and France imposed rules on enterprises regarding domestic employee policies (Tallberg 2004). Renneboog et al. (2008) stated that in the 1980s, investment funds in the United States and the United Kingdom began to examine corporations' socially responsible behavior. There are several events that put the CSR efforts on the map such as Earth Summit that was held by the

UN in Rio de Janeiro, Brazil, in 1992 and was followed up by the declaration for sustainable development in 2002. During the 1990s, the ideas of social reports also developed vigorously (Hys and Hawryz 2012).

To hold the companies accountable for their commitment on social responsibility, CSR reporting mechanism emerged. Referring to the dimensions that are used in defining CSR, CSR reporting is disclosing the activities of businesses that indicate the incorporation of economic, social, and environmental concerns into their company operations and interactions with stakeholders. CSR reporting may also be described as nonfinancial information on a company's interactions with its many stakeholders as well as its physical and social surroundings (Orzel 2020).

Stakeholders play a vital role in constituting the definition of CSR reporting. Stakeholders are individuals and groups, both inside and outside of corporations, who are interested in the outcomes of their operations and have expectations for greater openness from the firms (Benn et al. 2016). Some scholars see CSR reporting as a technique for managing legitimacy in response to stakeholder institutional demands (Michelon et al. 2015). Scholars have theoretically suggested that open CSR reporting is part of the conversation between an ethical corporation and its stakeholders, which will leverage favorable business reputation through the legitimization of corporate's behavior (Pérez 2015).

Based on some research (Pérez 2015), CSR reporting may help organizations improve their image in the eyes of stakeholders, which will result in the favorable impression in the perspective of society and affect their business positively, for example, increase sales or trust from the customers (Pérez 2015). There are companies that no longer use CSR reporting as a whim but rather a genuine tool of strengthening their own reputation. To some extent, a transition from the concept which predicated CSR reporting as a mandatory measure, even in the absence of regulations, could be seen. CSR reporting can be seen as a tool that assists businesses in measuring, understanding, and communicating their economic, environmental, social, and governance performance, as well

as in setting objectives and responding appropriately to changes more effectively.

According to Turkel and Akan (2015), CSR communication can also be defined as a process of anticipating stakeholders' expectations, articulating CSR policy, and managing various organizational communication tools designed to provide true and transparent information about a company's or brand's integration of its business operations, social and environmental concerns, and interactions with stakeholders. CSR communication, in a broader sense, might be defined as a tool-oriented activity that relates to how CSR is communicated through reports, codes of ethics, principles, and standards, as well as the editing of CSR message content in advertising and marketing material. CSR communication is thus critical in all CSR operations, from strategic CSR conceptualization and implementation to CSR planning and execution.

When taking the stakeholders' expectation, it implies that it is not always in accordance with established norms or laws. When the ambitions of greater society, as represented by stakeholders, are not satisfied, society has the power to enforce their desires by going outside the law.

These expectations or demands may stem from what is often disparagingly referred to as "conventional morality." Ignoring or failing to take any claims into account when applying ethical norms to business, society, and stakeholders can still constrain business in ways other than by law, for example, by practicing social pressure and moral sanctions (such as boycotts, defamatory of company brand image, or publicizing harmful corporate actions). Thus, these kinds of repercussions should be expected by truly listening to what stakeholders may have in their aspirations, as well as keeping the community informed of the good deeds that have been done through reports and other communication channels.

Due to the unrelenting pursuit of responsible reporting of nonfinancial components of business entities, there have been growing needs for guidelines for quality reporting. This is when Global Reporting Initiative (GRI) emerged. GRI is a set of guidelines of CSR reporting that emerged in 1997. During this time, the Social Accountability

8000 (SA 8000) standard, a social accreditation standard for industries and organizations worldwide, has also emerged. In the year 2000, the United Nations Worldwide Compact debuted on the global corporate reporting arena (Hedberg and Von Malmberg 2003). More of this type of information is now accessible for global business organizations to use in reporting their non-financial operations. CSR reporting has been increasingly relevant in recent years for reasons of accountability, transparency, and good business practice.

The benefits from providing CSR for the stakeholders and public and general have been understood by many corporate organizations particularly in terms of how they deal with environmental, social, and governance elements of operational activities. Now there are many international reporting guidelines available to help companies that have aspirations to be socially responsible and provide the stakeholders with the information that is comprehensive regarding their social responsibility.

Key Issues

At the beginning, the main concern of CSR was environmental issues that could threaten the future of the planet Earth and the survival of mankind (Frederick 2018). The concern that companies may fail to notice possible problems from their actions and take steps to avert them has spurred the need to hold companies accountable through CSR. Since then, CSR has grown in depth and no longer just focuses on environmental issue, but also research and examine the significance of social and economic aspects of human welfare. This development has now been well-recognized and established topic of scientific research.

In the CSR field, the concept of "butterfly effect" is also acknowledged. The butterfly effect is a metaphor for little, insignificant events that may have large, far-reaching social implications. When operating within a specific local culture, there is an expectation that businesses will exercise benevolence while trying to bring along their rewards in the form of products, services, and

jobs. However, in reality, the emergence of foreign or international business can threaten the status quo of local, political, and social orders. As a result, enterprises should be held accountable for the consequences of their activities on the environment and communities that may be unable to protect themselves against infractions.

The good cause objective behind CSR often links the CSR effort with altruism, and this has been highly debated. Being altruistic comes with the underlying assumptions that corporate must take responsibility beyond their business activities. There are no other interests or added value besides giving back and contributing to sustainable development, which means that CSR is associated with a firm doing good deeds such as corporate volunteering, creating a foundation, giving back to the community, and so on. However, in the current view of CSR, creating such stakeholder value is neither an altruistic endeavor, nor is it just the fulfillment of stakeholder interests. Rather, CSR is viewed as a management idea that may help the organization.

Thus, this understanding also imply the potential added values that could be earned by companies when implementing CSR. There are three approaches that can explain on why a company should continue to implement CSR activities: first, the instrumental approach/“it’s good for business” that refers to positive business case; second, the ethical approach/“it’s the right thing to do” that insists on what’s morally obligatory thing to do; and, third, the hybrid approach/“we should do good, both financially and ethically,” which integrated the previous two arguments that it is, at the very least, the correct thing to do both financially and morally.

The four grounds for the business case for CSR are as follows: (1) firm reputation and legitimacy, (2) equal employment opportunity and cost and risk reeducation, (3) competitive advantage, and (4) establishing win-win scenarios via synergistic value creation. To recapitulate, proponents of cost and risk reduction arguments argue that CSR helps a company to take advantage of tax breaks or avoid rigorous and burdensome government regulations, lowering its operational costs (Okpara and Idowu 2013).

Many studies (Jamali 2008) imply that when the conventional pillars of business ethics fail, organizations are asked to develop new corporate strategies to demonstrate their ethical standards. Authors have noted that the disclosure of CSR information is part of the discussion between an ethical company and its stakeholders that helps justify corporate behavior and thus contributes to the corporate’s stellar reputation based on the various theories such as the institutional/legitimacy and agency theories (Table 1) (De Georgen 2008). There are also other approaches like impression management theory that see CSR reporting of public vehicle to help a company to influence people’s perception on their image or product and services they sell (Pérez 2015).

Competitive benefit arguments suggest that by adopting certain CSR activities, a corporation might develop strong ties with its stakeholders and gain their support through decreased staff turnover, access to a larger talent pool, and consumer loyalty. As a result, a company will be able to distinguish itself from its competitors. A corporate can also benefit from the disclosure of their good performance of CSR through CSR reporting which might result in enhancement of their legitimacy and reputation.

The keys to publishing CSR reports include defining accountability for stakeholders, establishing trusting relationships with those stakeholders, and cocreating values. To accomplish this, a corporation must establish bilateral contact with stakeholders rather than providing information to them unilaterally. Companies that see their CSR report as nothing more than a tool to display convenient corporate information and hide difficult facts from the report will fail to acquire the trust of stakeholders. Instead of just introducing management institutions, such organizations should create targets for the material assignment of environmental, social, and governance (ESG) concerns and specify obstacles in the evaluation of yearly achievements.

Tanimoto (Idowu et al. 2015) indicated that it is critical to improve the quality, trustworthiness, and comparability of CSR reporting information for the following reasons:

CSR Reporting, Table 1 Corporate reputation and stakeholder CSR reporting literature gaps and future research directions (Pérez 2015)

Theoretical approach	Perspective	References
Institutional/legitimacy theory	CSR reporting as a legitimacy and reputation management tool responding to pressures by stakeholders and driven by corporate identity communications	Patten (1992), Deegan (2002), de Quevedo et al. (2007), King and Whetten (2008), Nikolaeva and Bicho (2011), and Michelon (2011)
Impression management theory	CSR reporting as a public relations vehicle aimed at influencing people's perceptions	Gray et al. (1993), Elkington (1997), Hoogheemstra (2000), and Piechocki (2004)
Reputation risk management theory	CSR reporting conceived as both an outcome of and part of reputation risk management processes	Friedman and Miles (2001), Bebbington et al. (2008), and Unerman (2008)
Agency theory	CSR reporting as an essential tool for information exchange, the reduction of asymmetries, and the promotion of greater corporate transparency	Fama (1980), de la Fuente and de Quevedo (2003), Espinosa and Trombetta (2004), DeTienne and Lewis (2005)
Signaling theory	CSR reporting as a way to signal corporate reputations to stakeholders	Spence (1974), Toms (2002), and Watson et al. (2002)

- If each firm provided data based on its own criteria, it would be impossible to compare that data to data from other companies.
- If some information represents the performance of the central office while other information represents the performance of consolidated entities, it becomes difficult to indicate corporate performance as a whole due to a lack of standardized data.
- To earn more credibility from stakeholders, the application of GRI guidelines or the acceptance of third-party assurance is required to validate and certify the CRS report.

When firms include CSR into the heart of their company plan, CSR becomes more than simply an optional add-on activity, and they must then focus on holistic and integrated performance evaluation. When this occurs, issuing an integrated report rather than separate reports on financial and CSR becomes more common.

Another issue is how much control and facilitation the national government should have over CSR reporting. Some nations have public regulations requiring or encouraging publicly traded corporations to report non-financial concerns. The expectation of such a strategy is that strategic reporting will become a driving force in increasing stakeholder trust

and increasing value for both the firm and its stakeholders.

Summary

There are various approaches in defining CSR, but, in general, CSR could be seen as companies' efforts to contribute to sustainable development. Sustainable development is defined as development that satisfies the requirements of the present generation without affecting future generations' ability to satisfy their own needs and focuses on how to achieve the integration of economic, environmental, and social stringent (Kim et al. 2014). To hold the companies accountable for their commitment on social responsibility, CSR reporting mechanism was founded. By the definition, CSR reporting is disclosing the activities of businesses that indicate the incorporation of economic, social, and environmental concerns into their company operations and interactions with stakeholders (Orzel 2020).

According to certain study (Pérez 2015), CSR reporting may leverage a company's favorable image in the eyes of stakeholders, resulting in a positive reputation in the eyes of society, and affect their business positively, for example, increase sales or trust from the customers (Pérez 2015). Scholars have argued that the disclosure of

CSR information is part of the conversation between an ethical company and its stakeholders, which helps legitimize corporate behavior and therefore contributes to the corporate's positive reputation, depending on multiple theories such as the institutional/legitimacy and agency theories (De Georgen 2008). Companies that see their CSR report as nothing more than a tool to display convenient corporate information and hide difficult facts from the report will fail to acquire the trust of stakeholders.

Definition

Corporate social responsibility (CSR) can be defined as a “concept whereby companies decide voluntarily to contribute to a better society and a cleaner environment” (European Commission 2001, p. 4). The basic notion of CSR “is the idea that it reflects the social imperatives and the social consequences of business success” (Matten and Moon 2008, p. 405). In that sense, the European Commission presented a new definition of CSR as “the responsibility of enterprises for their impacts on society” (European Commission 2011, p. 7).

The Communication of the European Commission at the end of 2011 underpinned the adverse effects of the economic and social crisis, as they have damaged consumer confidence and levels of trust in business and “have focused public attention on the social and ethical performance of enterprises” (European Commission 2011, p. 5).

CSR is an umbrella term overlapping with some and being synonymous with other conceptions of business–society relations (Matten and Crane 2005). The basic concept of social responsibility is related to moral and ethical issues concerning behavior and business decision-making, and to complex issues as environmental protection, safety, and health at workplace; relationship with local communities and consumers (Branco and Delgado 2011) is seen as a win–win strategy, as it potentially increases a company’s profitability and the well-being of stakeholders (Merino and Valor 2011). The core idea of this tool is the mutual dependence between the company and society, which in turn creates value for both, and can also represent the image of excellence both in the internal and external environment (Gholami 2011).

The CSR importance has “increased among managers, investors, shareholders, creditors, suppliers, customers, and policymakers due to accounting scandals over the past two decades” (Kiliç 2016, p. 550). Thus, there is a growing awareness that companies must be socially responsible and, to that extent, CSR “has become a key part in the strategies of companies around the globe to promote sustainable development” (Nawaiseh et al. 2015, p. 99).

There are a variety of CSR’s definitions, but most definitions make explicit reference to sustainable development and integrate the three pillars of the Brundtland Report: environmental, social, and economic well-being (Lamarche and Bodet 2018, p. 155). Thus, a wide range of labels, concepts, and constructs have been used to “describe and theorize the social phenomena that correspond to CSR—e.g., Businessmen Responsibility, Corporate Social Performance, Corporate Social Responsiveness, The Triple Bottom Line, Corporate Stakeholder Responsibility or Corporate Citizenship” (Gond and Moon 2011, p. 3), as a result of this dynamic, overlapping, and contextual character (*ibid.*).

The literature shows that there is no standardized definition of CSR and, although new concepts such as *corporate sustainability* and *corporate citizenship* have emerged, they are all related, and CSR remains the dominant concept (Carroll and Shabana 2010). In fact, the different approaches to CSR emphasize their contribution to sustainability (Lungu et al. 2011). In this sense, *sustainable development* is defined as a “model of triple-bottom-line” (Ebner and Baumgartner 2006, p. 3) which believes in an equal consideration of economics, social and ecological aspects, without compromising the ability of future generations to meet their own needs (Ebner and Baumgartner 2006; WCED 1987). As a result, *business success* is defined “as more than just maximizing profits and includes social and environmental benefits collaboratively aimed for all stakeholders” (Schaltegger and Burritt 2018, p. 254).

Most of the business ethics literature has emphasized the philanthropic character of voluntary social and environmental activities of companies (Carroll 1979). But *business ethics* “is more than just virtue, integrity, or character, it involves the application of one’s understanding of what is morally right and truthful at a time of ethical dilemma” (Lewis 1985, p. 383). In this sense, the literature indicates that “many of the business ethics failures in recent memory can be attributed to financialization,” or the vice in which “moral agents are overcome by inordinate desire for

wealth or greed” (Gerde and Michaelson 2018, p. 3).

There is significant variation among countries about CSR meaning. As stated by Votaw (1972, p. 25), CSR “means something, but not always the same thing, to everybody” and takes different forms in different countries (Brammer et al. 2012). In other words, “in European countries, social responsibility is said to be typically understood as the integration of socially responsible practices into the very activities of business and wealth creation” (Blasco and Zølner 2010, p. 217), but in the USA, a philanthropic model predominates whereby wealth is first created and then channeled through foundations into social causes (Montuschi 2004). Countries like India, for example, is dominated by family-owned companies, thus attributes charity to CSR and philanthropic activities (Bhaduri and Selarka 2016).

The Green Paper presented by the Commission of the European Communities (European Commission 2001) indicates the two dimensions of CSR – internal and external.

At the level of the internal dimension, the socially responsible practices of companies essentially involve workers and are related to issues such as investment in human capital, health, safety, and change management; while environmentally responsible practices relate in particular to the management of the natural resources used in the production process (European Commission 2001). The external dimension of a company’s social responsibility “extends beyond the doors of the company into the local community and involves a wide range of stakeholders in addition to employees and shareholders: business partners and suppliers, customers, public authorities and NGOs representing local communities, as well as the environment.” (European Commission 2001, p. 12).

The literature shows that CSR continues to be the widely used concept in the relations between business and society. It is presented as the “‘corporate’ or ‘organization’ component of sustainable development, aimed at providing company-level solutions to the worldwide ecological and social crisis” (Lamarche and Bodet 2018, p. 155). Thus, the concept of CSR seems to

“has a bright future because at its core, it addresses and captures the most important concerns of the public regarding business and society relationships” (Carroll 1999, p. 292), and should be philosophically aligned with ethics (Gerde and Michaelson 2018) and although CSR is a “controversial concept, everybody in the academic and business spheres agree that it is a fundamental strategy for achieving the sustainable development that our globalized world needs” (Souto 2009, p. 38).

Introduction

Corporate social responsibility (CSR) is not a new concept (Othman and Ameer 2009). CSR has been “under constant development since the beginning of 20th century” (Denisov et al. 2018, p. 63). In fact, “over the decades, the concept of corporate social responsibility has continued to grow in importance and significance” (Carroll and Shabana 2010, p. 85), and it is difficult to define CSR as a result of its “dynamic, overlapping and contextual character” (Gond and Moon 2011, p. 3).

In a historical perspective, the CSR concept has evolved significantly over the past 50 years and can be understood as an evolving concept (Carroll 1999). The initial idea argued that the sole purpose of a company was to *maximize profit* (Friedman 1970). In this sense, the only responsibility of business is “to use its resources and engage in activities designed to increase its profits so long as it stays within the rules of the game, which is to say, engages in open and free competition without deception or fraud” (Friedman 1970, p. 178). But while Friedman’s ideas are better known, his predecessor Theodore Levitt warned the business world about the dangers of social responsibility (Levitt 1958). Levitt (1958) argued that companies should aim to improve productivity and increase profits by acting honestly and in good faith, considering that social problems should be the responsibility of the state.

In Howard R. Bowen’s (1953) *Social Responsibilities of the Businessman* seminal book (Bowen 1953) one of the earliest classical

definitions of CSR emerged, marking the modern era of social responsibility (Carroll 1979). Bowen (1953, p. 6) defines CSR as “the obligations of businessmen to pursue those policies, to make those decisions, or to follow those lines of action which are desirable in terms of the objectives and values of our society of entrepreneurs to pursue policies, make decisions or follow lines of action that are compatible with the ends and values of our society.” In other words, this author considers that, because of their increasing size and proliferation, they had acquired a broad influence on the development of societies, and therefore this increased power should be accompanied by an increase in responsibility with CSR being the obligation of entrepreneurs adopts policies and practices that are appropriate to the goals and values of society (Bowen 1953).

According to Carroll (1999), the 1960s was marked by a significant increase in the attempt to formalize or define CSR and its importance for business and society. In this sense, Davis was one of the first and most extraordinary writers during this period to define CSR (Carroll 1999). This author defines social responsibility as the “businessmen’s decisions and actions taken for reasons at least partially beyond the firm’s direct economic or technical interest” (Davis 1960, p. 70).

McGuire (1963, p. 144), another contributor to the definition of social responsibility during the 1960s, argued that “the idea of social responsibilities, supposes that the corporation has not only economic and legal obligations but also certain responsibilities to society which extend beyond these obligations.” One of the characteristics of the 1960s was the absence of any interaction of social responsibility with financial performance (Lee 2008).

At the 1970’s the term *responsiveness* came to follow the concept of social responsibility when the need arose to build tools that could measure the social performance of companies. Thus, “corporate social *responsibility*, *responsiveness* and *performance* became the centre of discussions” (Carroll and Shabana 2010, p. 87). Manne and Wallich (1972) also made a significant

contribution to the CSR definition of CSR in the 1970s by introducing the concept of “*voluntary activities*.”

According to Carroll (1979), CSR included the idea that the corporation has not only economic and legal obligations but ethical and discretionary (philanthropic) responsibilities as well. Carroll’s “Three-Dimensional Conceptual Model of Corporate Social Performance” (1979, 1991) was the initial model of corporate social performance. This model consists of an integration of three aspects:

- Definition of social responsibility
- Identification of the social problems to which these responsibilities are linked (such as consumerism, environment, employment discrimination, product safety, occupational safety, and health)
- Philosophy of responsiveness (mode or strategy behind the corporate response to social responsibility), and social issues (reaction, defence, accommodation, and pro-action).

This conceptual model, widely accepted, describes four dimensions of social responsibility:

- *Economic* (the business institution is the basic economic unit in our society and as such, the responsibility to produce goods and services that society wants and sell them at a profit)
- *Legal* (laws and regulations, under which companies are expected to function)
- *Ethics* (society has business expectations beyond legal requirements being that ethical responsibilities are poorly defined and hence are among the most difficult to deal with)
- *Philanthropic* (they are responsibilities over which society has no clear message for the business)

Carroll (1991) argues that these four categories of CSR can be described as a pyramid, where economic responsibilities are the basis on which all others are based and without which they cannot be achieved, and discretionary/philanthropic responsibilities constitute the vertices. In other

words, Carroll (1991, p. 43) stated that “CSR firm should strive to make a profit, obey the law, be ethical, and be a good corporate citizen.”

The 1980s marked the beginning of the *business/business ethics* phase, where the focus became on the promotion of business ethics (Frederick 2008), initiating the link between CSR and corporate financial performance (Lee 2008). In this sense, *business ethics* refers to “interaction of ethics and economy for the good life in society” (Gerde and Michaelson 2018, p. 4).

Drucker (1984) concluded that profitability and accountability are complementary notions, as well as the notion that it is desirable for a business to “convert” social responsibilities into business opportunities.

The 1990s and 2000s became the era of global *corporate citizenship* (Frederick 2008).

The beginning of the twenty-first century was marked by a series of scandals, such as Enron; the Wall Street financial scandal in 2008; the scandal that hit the international financial markets around the London Interbank Offered Rate – LIBOR – in 2012; and the Volkswagen scandal, in 2015. It is also in this century that the concepts of *sustainability* or *sustainable development* emerge (Carroll and Shabana 2010).

However, if today’s CSR is associated with sustainability, “its origins lie in defensive measures intended to respond to the societal criticism expressed by various social groups in face of the companies’ economic and social ‘irresponsibilities’” (Lamarche and Bodet 2018, p. 157).

Thus, CSR has been gaining importance in business life (Lungu et al. 2011). Lungu et al. (2011, p. 460) stated that the “the business sector should play a proactive role in society, in addition to its economic purpose of making profits.”

Lantos (2001) concluded that there are three types of CSR:

- *Ethics* (minimum level of social responsibility and minimization of damages)
- *Strategic* (financially benefiting the business serving society in an extra-economic way)

- *Altruistic* (is uncertain, even irrelevant, and is outside the scope of corporate responsibility; it assumes that the company does not benefit from each other)

There are generalized differences in the understanding of CSR in a wide variety of countries, from the most developed to the least developed (Bhaduri and Selarka 2016):

- Canada, companies have developed CSR strategies in response to a growing increase in issues such as sustainable investments
- Asian countries, such as Hong Kong and Singapore, CSR means transparency and accountability, taking into account work and community
- Israel, companies cannot see the need to develop and provide specific information on CSR activities

Over the last half-century, there have been numerous conceptual changes of CSR. For example, *corporate citizenship* used as a synonym of CSR (Matten and Crane 2005), or the almost systematic use, since the 1990s, of the concept of *stakeholders* in the definition of CSR (Gond and Moon 2011).

Table 1 lists the numerous conceptual changes of CSR over the last half-century and illustrates the successive piling of social responsibility, managerial and academic concepts since the 1920s (Gond and Moon 2011).

Although these transformations have generally reflected solid conceptual developments (Wood 1991; Carroll 2008), changes in management practices and visions also reveal the spirit of the age as they accompany the management cycle and fashions (Economist 2005; Abrahamson 1996).

In summary, CSR has evolved significantly over the decades, and its definition is difficult due to the constant mutation of society. However, there are generalized differences in a great diversity of countries in relation to the understanding of CSR (Bhaduri and Selarka 2016) and the literature shows that CSR continues to be the widely used

CSR: Evolution of Concept, Table 1 Illustrative CSR concepts and definitions

Author(s)	Construct proposed	Definition provided	Focus/Perspective
Bowen (1953)	Businessmen social responsibility	It refers to the obligations of businessmen to pursue those policies, to make those decisions, or to follow those lines of actions which are desirable in terms of the objectives and values of our society (p. 6)	Businessmen/ Normative/ Institutional
Davis (1960)	Corporate social responsibility	Businessmen's decisions and actions taken for reasons at least partially beyond the firm's direct economic or technical interest (p. 70)	Businessmen/ Normative/Beyond expectations
McGuire (1963)	Corporate social responsibility	The idea of social responsibilities supposes that the corporation has not only economic and legal obligations but also certain responsibilities to society which extend beyond these obligations (p. 144)	Corporation/ Normative/Beyond expectations
Walton (1967)	Corporate social responsibility	In short, the new concept of social responsibility recognizes the intimacy of the relationships between the corporation and society and realizes that such relationships must be kept in mind by top managers as the corporation and the related groups pursue their respective goals (p. 18)	Top managers/ Normative/ Institutional
Friedman (1970)	Business social responsibility	There is one and only one social responsibility of business – to use its resources and engage in activities designed to increase its profits so long as it stays within the rules of the game, which is to say, engages in open and free competition without deception or fraud (p. LAST)	Normative/Critical/ Profitfocus
Eells and Walton (1974)	Corporate social responsibility	In its broadest sense, corporate social responsibility represents a concern with the needs and goals of society which goes beyond the merely economic. Insofar as the business system as it exists today can only survive in an effectively functioning free society, the corporate social responsibility movement represents a broad concern with business's role in supporting and improving social welfare (p. 247)	Normative/ Institutional/ Ecological/Welfare focused
Frederick (1978 [1994])	Corporate social responsiveness	Corporate social responsiveness refers to the capacity of a corporation to respond to social pressures (1994, p. 247)	Corporation/ Institutional
Carroll (1979)	Corporate social responsibility	The social responsibility of business encompasses the economic, legal, ethical, and discretionary expectations that society has of organizations at a given point in time (p. 500)	Business/Integrative
Epstein (1987)	Corporate social responsibility	Corporate social responsibility related primarily to achieving outcomes from organizational decisions concerning specific issues or problems which (by some normative standard) have beneficial rather adverse effects on pertinent corporate stakeholders. The normative correctness of the products of corporate action have been the main focus of corporate social responsibility (p. 104)	Corporations/ integrative/Normative
Frederick (1986)	Corporate social rectitude	Corporate social rectitude embodies the notion of moral correctness in actions taken and policies formulated. Its general value referent is that the body of sometimes dimly or poorly expressed but deeply held moral convictions that comprise the culture of ethics (p. 135)	Corporation/ Normative

CSR: Evolution of Concept, Table 1 (continued)

Author(s)	Construct proposed	Definition provided	Focus/Perspective
Wood (1991)	Corporate social performance	A business organization's configuration of principles of social responsibility, processes of social responsiveness, and policies, programs, and observable outcomes as they relate to the firm's societal relationships (p. 693)	Organization/ Integrative
Maignan and Ferrell (2000)	Corporate citizenship	The extent to which businesses meet the economic, legal, ethical, and discretionary responsibilities imposed on them by their stakeholders (p. 284)	Corporation/ Stakeholder/ Integrative
McWilliams and Siegel (2001)	Corporate social responsibility	Here, we define CSR as actions that appear to further some social good, beyond the interest of the firm and that which is required by law (p. 117)	Corporation/Social good/Beyond requirements
Matten and Crane (2005)	Corporate citizenship	Corporate citizenship describes the role of the corporation in administering citizenship rights for individuals (p. 173)	Corporation/Political/ Institutional
Campbell (2006)	Corporate social responsibility	I view corporations as acting in socially responsible ways if they do two things. First, they must not knowingly do anything that could harm their stakeholders. Second, if they do harm to stakeholders, then they must rectify it whenever it is discovered and brought to their attention (p. 928)	Corporation/ Stakeholder/ Institutional/ Minimalist
Crouch (2006)	Corporate social responsibility	Behavior by firms that voluntarily takes account of the externalities produced by their market behavior, externalities being defined as results of market transactions that are not themselves embodied in such transactions. CSR is essentially _corporate externality recognition (p. 1534)	Corporation/ Transactional/ Externality focused
Basu and Palazzo (2008)	Corporate social responsibility	We can define CSR as the process by which managers within an organization think about and discuss relationships with stakeholders as well as their roles in relation to the common good, along with their behavioral disposition with respect to the fulfillment and achievement of these roles and relationships (p. 124)	Stakeholders/ Commongood/ Integrative

concept in the relations between business and society.

Summary

CSR has always been perceived as a questionable concept. There is no standardized definition of CSR, mainly because it has no specific limits. CSR is generally perceived as a strategy which is economically beneficial in the long term. CSR is regulated through national and international self-regulatory measures without binding legal force (*soft law*) (Birindelli et al. 2015).

New methodologies are needed to measure corporate social responsibility. The literature (Margolis and Walsh 2003) identified sampling problems and raised concerns about the reliability and validity of measures of corporate social performance and financial performance, stressing the importance of developing models incorporating omitted variables, testing of measurement mechanisms and contextual conditions, and causal relationships between social performance and financial performance.

Despite academic literature stating a growing importance in relation to CSR, we have now witnessed a state of global alert since the new US President Donald Trump took office on

January 20, 2017. There are those who speak in “civilizational retrocession.” There are multiple media reports about Trump’s numerous negationist initiatives regarding the administration of former President Barak Obama, including environmental issues. In this regard, Trump even wrote on Twitter that “global warming was invented for and by the Chinese in order to make American industry uncompetitive.” We may be faced with a new CSR paradigm. New research should be directed at exploring the extent to which US environmental policy changes the concept of CSR.

Faculty of Tourism, İzmir Katip Çelebi University, İzmir, Turkey

Definition and Conceptual Framework

The relationship of culture, tourism, and sustainability in other words, social or socio-cultural sustainability of tourism including sustainable cultural heritage management for tourism is basically constructed upon the vulnerable and sensitive issues related to people: their values, their history, identity and living styles, their behaviors, attitudes, perceptions; their acceptance or rejection levels; and their emotions towards tourism.

The socio-culturally sustainable tourism system is comprised of all these “people” issues given priority while ensuring the “well-being” and “quality of life” of all stakeholders being involved to some extent, in the exchange of tourism products and services. In this system, the benefits provided by tourism and the costs incurred by the stakeholders concerned are to be conducted at tolerance limits for inhabitants (or beneficiaries) who are involved in decision-making and serving and users (or tourists).

The given description is inspired by the tourism literature in general and in particular by Hughes (1995) and Uysal et al. (2012). The latter two authors analyze the literature related to “cultural construction of sustainable tourism” and “the tourist area life cycle (TALC) and its effect on the quality-of-life (QOL) of destination community.” The essential points to consider for the construction of ethically correct and ever-evolving socio-culturally sustainable tourism systems are emphasized. Hughes (1995) studied the cultural construction of sustainable tourism considered along with the economic and environmental dimensions not separately, but together with the socio-cultural dimension and with the inclusion of all stakeholders. In the study by Uysal et al. (2012), the tensions or harmony in respect to the tourist area life cycle and the perception of quality of life at the destination are mentioned to show a positive relationship. In summary, as the life cycle of the destination evolves, quality of life increases parallel to increases in income and other benefits. In contrast, as the life cycle goes through a period of decline, the losses (overcrowding, pollution, etc.) and costs incurred by the destination increase due to the negative impacts of tourism. Also the quality of life at the destination declines.

Another aspect of the management of socio-culturally sustainable tourism is the cultural heritage management. Cultural heritage, tangible or intangible, represents the identity and cultural values of a group of people in a particular area. In the framework of cultural tourism or heritage tourism, this kind of valuable resource becomes commercially important as well. The advantages that cultural heritage tourism brings such as the preservation, protection, and revaluation of the tangible and intangible culture are desirable.

However, the undesired effects such as depreciation and destruction of heritage and the over-construction and overcrowding in the area and commodification and acculturation may occur in the case of unsustainable management. Attempts to manage the positive and negative results of cultural heritage management at the destination level may not be sufficient. A universal acceptance of heritage thus paves the way for greater protection of the universally acknowledged cultural heritage.

Socio-Culturally Sustainable Heritage Management

UNESCO (The United Nations Educational, Scientific and Cultural Organization) has the essential mission of officially registering the universally approved tangible and intangible cultural heritages all around the World. For a more sustainable management of cultural heritage and thus socio-culturally sustainable tourism, some descriptions have been indicated relating to the issues of the destination’s “socio-cultural carrying capacity” and “Limits for acceptable change” (LAC) in a study document realized by UNESCO (De Ascaniis et al. 2018). “Socio-cultural carrying capacity” is described as: “A tourism development threshold that draws a line between a development stage that does not create negative socio-cultural impacts on host communities and a development stage that does create negative socio-cultural impacts.” It is also added that: “When tourism operates beyond locals’ socio-cultural carrying capacity, there is a risk that host communities will act against tourism and tourists.” Also “LAC are usually set by local communities and draw the lines between what is acceptable and what is unacceptable in terms of socio-cultural tourism impacts in their locality” (De Ascaniis et al. 2018, p. 37). These two indicators or borderlines, as may be called, are important to consider while constructing a sustainable socio-cultural tourism and cultural heritage management system.

UNESCO World Heritage Convention accepted in 1972 by 24 countries was ratified in 2017 by 193 countries. UNESCO continues its

mission with its regularly modified “Operational Guidelines for the Implementation of the World Heritage Convention” and continue to lead the cultural heritage management worldwide. Improvements were made by The Budapest Declaration in 2002 which “seeks to ensure an appropriate and equitable balance between conservation, sustainability, and development” with 4Cs: “Credibility” of the List, effective “Conservation,” and increased “Capacity” and “Communication.” In 2007, a “fifth C” for “Communities” was added. In 2017, 1052 properties in 165 Member States were inscribed on the list, and there are also 1710 properties on Tentative Lists. Being on the list increases the advantage in terms of marketing and credibility of the cultural, natural, and mixed heritages (De Ascaniis et al. 2018).

Further local studies are made about the sub-indicators to reconcile sustainable tourism and cultural heritage management while trying not to create socio-cultural tension at the destinations. For sustainability in tourism, Landorf (2009) emphasized the need for a broader and more inclusive WHS (World Heritage Sites) structure of planning which includes the strategic planning and implementation and evaluation phases. A suggestion of a management plan is made including the main topics and indicators of: “Situation analysis (Tangible heritage, intangible heritage, land use and ownership, demographic characteristics, economic characteristics, economic benefits, heritage tourism activities, capacity of infrastructure, visitor details, integration); Strategic Analysis (Long term orientation, economic goals, environmental goals, social/community goals, heritage development goals, strategic alternatives, objectives support goals, capability based objectives, equitable objectives, quantifiable objectives); Values and Attitudes (Local values and attitudes, residents issues, attitudes to heritage, quality of life, vision alignment); Stakeholder participation (Stakeholder relationships, government participation, government influence, non-government participation, non-government influence, local participation, local influence, visitor participation, visitor influence)” (Landorf 2009, p. 66). In addition, the level of conformance of each WHS to these indicators is marked in the study.

Besides increasing the credibility of the destination and visits to that destination (De Ascaniis et al. 2018, Santa-Cruz and López-Guzmán 2017), cultural heritages are mentioned as a potential sustainability measure to increase tourism activities and income during the low season as indicated in a study carried out in Italy on the Island of Sardinia (Giudici et al. 2013). Santa-Cruz and Lopez Guzman (2017) emphasized the importance of tangible cultural heritage for the development of sustainable tourism as well as for the conservation of the heritage. In their study, they revealed that the tourist coming for cultural heritage is more highly educated, with a higher level of income, originating from many different nationalities. Additionally, the reasons for cultural heritage tourist’s visits are shown as seeking for new discoveries or historical sites or even their past hereditary. The study was carried out to discover the behaviors and travelling habits of the tourists during the high season.

As a more specific field of cultural tourism, a study was conducted on understanding the art museum visitors by Stylianou-Lambert (2011). Findings include a classification of the “filters” for the perception of the museums at home and at the destination: “Professional, art-loving, self-exploration, cultural tourism, social visitation, romantic, rejection, and indifference.” The idea of the “tourist gaze” that is adopted at the destination (Urry 2008) is supported and additionally it is indicated that their other “gazes” or “filters” are not abandoned while they are at the foreign destination. A further finding of this study concluded that if people do not visit museums at home, they will not visit them abroad either.

Another important issue about the management of the heritage in terms of sustainable tourism is the ownership and management of intangible cultural heritage for tourism purposes. When used in the framework of tourism, the intangible values as a part of the local daily life of inhabitants may be harmed and even completely changed by the customer value system. While the heritage values are commercialized, if they lose their originality and original value, they become objects of exchange which is called commodification of culture (George 2010, p. 381). Unfortunately, it is unavoidable sometimes. George

(2010) suggests creating a community cultural heritage fund in order to avoid this type of unsustainable result. In this way, it is supported that if the community is creator and owner of its own cultural resources, then there will be a much more fair distribution of benefits and protection of the values and rights. Nasser (2003) also suggests that sustainable tourism implications may be a solution to reconcile the objectives of commercial gain, development, building, reconstruction with the conservation, and protection of cultural heritage values.

Findings of a study by Van der Borg et al. (1996) show that, if the management is not sustainable in the destinations with heritage sites, it does not go further than the promotion. Then, mostly as a result of bad management, costs exceed the benefits and finally, the economic problems arise. Then tourism becomes a threat to the heritage itself, to economy, and to quality of life of the residents. The control of visitor flows is one of the guidelines suggested by the authors as a solution in their study conducted at seven European art cities of heritage: Aix-en-Provence, Amsterdam, Bruges, Florence, Oxford, Salzburg, and Venice.

The studies of cultural tourism are summed up under topics of “cultural consumption, cultural motivations, heritage conservation, cultural tourism economics, anthropology and the relationship with the creative economy” (Richards 2018). In the same study, the movement for the recent research and trends in cultural tourism is noted to be from tangible towards intangible heritage. In addition, the indigenous and minority groups are also the subject of a large coverage of geographical areas. Another point is the changing terms in social science such as “mobilities, performance, and creative turns” which evolve identification of “cultural tourism.” Future studies are suggested to develop around the transmodern cultures and the effects of new technologies.

Another study underlines the positive effect of cultural heritage on redefining the residents’ sense of place if the process of preservation and rehabilitation are managed sustainably. The same study discusses the politics of heritage and culture in the framework of the preservation and

rehabilitation in the Balkans and Turkey where many globally important tangible and intangible heritages of UNESCO are situated (Luke 2013).

In a study enlightening the impacts of tourism on the value of cultural heritage, it is stressed that cultural heritage management at destinations with developing economies should be culturally and naturally sensitive. It is required to create a sustainable tourism management system with a framework including an understanding of the spirit of the place and including all the stakeholders with a coordinated approach. The symbiotic relationship between people, environment, economy, and multisectoral nature of the tourism industry is indicated to be possible solely by this coordinated and inclusive approach to realize the sustainable development goals (Imon 2017).

An earlier study also indicated the importance of the “participation” for sustainable management tourism in all its aspects. Called “question of the commons” as mentioned by Briassoulis (2002), the overuse and misuse of the commons (the natural, cultural, and all kind of resources used and available for the tourism industry); the social justice problems (distribution of the benefits and the costs) may generate even the destruction, underutilization, and even abandonment of the facilities. So it is emphasized that the participation of all parties to the decision making and implication of the frameworks and systems of sustainable management of tourism is important.

Socio-Culturally Sustainable Tourism Management: Examples from Case Studies

As noted at the beginning, in the description of this part, the importance of tourist-resident relationships and interactions, sharings, and perceptions is underlined by a quite important part of the sustainability of cultural tourism case studies (Poria et al. 2013; Lin et al. 2017; Rasoolimanesh et al. 2017; Liang and Hui 2016; Styliadis et al. 2014; Lee 2013).

Findings of the tourists’ perceptions of WHS (World Heritage Site) designated heritage sites by Poria et al. (2013) conclude that the cultural

heritage categorization of tourists are in line with UNESCO criteria as “culturally famous” with its “significance to humankind.” Other responses of interviewees included that the heritage site “need not be ancient or objectively authentic” and “not required to be located in situ.” The perceptions of advantages and disadvantages of the site designation as WHS are mostly about its marketing value increase such as increase in sites’ popularity, price increase in housing/real estate in the area, unwillingness to continue to live in the area because of the overcrowdedness occurring as a result of tourist traffic.

On the contrary, the study of Styliadis et al. (2014) on the residents’ perspective and its impacts on the sustainability of tourism indicate that the economic, socio-cultural, and environmental impacts as well as the place image perceived positively by the residents play a positive role on their support of tourism development.

Lee (2013) emphasizes the importance of “community involvement” and “community attachment” of the residents for the sustainable tourism development for a case study realized in Taiwan.

A study carried out in Malaysia’s rural and urban WHS destinations in order to discover the residents’ perceptions on their community participation and support for tourism development showed that there was more appreciation and support for tourism at the urban site than the rural. The development of tourism thus the level of awareness for it was recorded to be higher in the urban site. The study focused on the importance of community participation in the decision-making process of tourism development and the conservation of WHS (Rasoolimanesh et al. 2017).

Recent studies bring forward value co-creation which includes resident-tourist interactions (Lin et al. 2017). The study of Lin et al. (2017) shows that in the case of positive perceptions of tourism development and life satisfaction, residents are more eager to value co-creation with the tourists. Otherwise, if the costs of tourism development are higher, residents are reluctant to participate in co-creation.

A study conducted of the residents’ attitudes towards tourism development in China shows that

the new TQOL (Tourism Quality of Life) measures include and prioritize the nonmaterial family and personal well-being issues. Additionally, the attitudes of the residents change according to their status; if they are living there for to make a living or as a place simply to live (Liang and Hui 2016).

Socially Sustainable Tourism Management

First, the tourist of today (at least in western countries) travels much more than the tourist of the past and it is possible that the tourist of tomorrow will travel even more frequently. Therefore, travelling, which was considered a “luxury good” in the past, is nowadays an integral part of people’s lives (Stylianou-Lambert 2011).

The motto of the ISTO (International Social Tourism Organization) is “A fair and sustainable tourism for all.” ISTO is working for the inclusion and the right for participation of all without any discrimination to tourism activities on both supply and demand sides. ISTO defends that even if people have budgetary or other limiting reasons to participate, everybody has the right to have holidays and benefit from the touristic offer during their holidays. In order to facilitate the inclusion and participation, ISTO organizes projects, for example, for youth tourism in Europe, for students with a limited budget in Africa, for the senior people, for accessible tourism (for disabled), and for families and applies them in different areas of the world (oits-isto.org, ISTO 2016–2017). Many studies exist explaining the importance, motivations, and benefits of participation of all people to tourism and the right for “tourism for all” (McCabe 2009; McCabe and Diekmann 2015; Minnaert et al. 2009, 2010; Carneiro et al. 2013).

The philosophy of ISTO is indicated to be in line with the SDGs (Sustainable Development Goals) (oits-isto.org). The 17 Sustainable Development Goals with their 169 subtargets are set by the agreement of United Nations in 2015 for Agenda 2030. The framework is set in order to end poverty, fight inequality and injustice, and fix climate change. And tourism is reported to having

the potential to contribute to meet all the goals directly or indirectly as it is an industry with an economic power representing 10% of world GDP, 30% of services exports, and 1 out of every 10 jobs in the World. The 17 goals are set as “no poverty,” “zero hunger,” “good health and well-being,” “quality education,” “gender equality,” “clean water and sanitation,” “affordable and clean energy,” “decent work and economic growth,” “industry, innovation, and infrastructure,” “reduced inequalities,” “sustainable cities and communities,” “responsible consumption and production,” “climate action,” “life below water,” “life on land,” “peace and justice,” and “partnership for the goals” (Tourism for SDGs). An example case: The Via Via Tourism Academy created some “Joker” projects of sustainable tourism at an inclusive level by integrating the SDGs: Smiles Tour Guide Training in Malawi, integrated SDGs, 8 decent work and economic growth, 4 quality education, 11 sustainable cities and communities, and 17 partnerships for the goals. Entwiga Community experience in Uganda; SDGs integrated; 8, 11, 10 reduced inequalities, 17 (SDGityourself 2017).

Similarly, Neto (2003) attracted the attention to “poverty alleviation” and “community participation” at the tourism practices mentioning a more social sustainability approach moving beyond the environmental protection. Chok et al. (2007) discussed the pro-poor tourism and tourism’s impact over poverty alleviation analyzing the discourse of the global politically involved participation and inequality problems. The authors have underlined that tourism is not a solution to all economic problems of a country. Nevertheless, the high potential of sustainable tourism development to overcome the negative issues such as political problems, inequalities, war, lack of security, and many others are not denied as the examples which struggle for existence given in this study. The key point is in creating agreements of more ethical and altruistic models of sharing the benefits.

It is impossible to implicate the SDGs properly on any field including tourism, without deeply understanding that the philosophy of sustainable development is primarily people and inclusion oriented, then follows the benefits – even the

unattended. The way to teach this reality to people, businesses, governments passes from education. Cotterell et al. (2019) put emphasis on the educational deficiency and necessity for the SDGs and tourism reconciliation. The authors select and exemplify the very few studies realized on each SDG and its integration with tourism.

Last, but not least, studies having a “people” side in the framework of sustainable tourism development include various elements, for example, related to local food and sustainable tourism experiences such as “cittaslow” which is encouraging the development of slow cities that keep their historical, natural, socio-cultural, and touristic features (Ekinci 2014). Another study shows that local food products bought at the destination represent for the tourist not only a symbol of the place in memory but also a benefit as an experience providing a deeper meaning of “self” (Sims 2009).

Client service; Consumer service; Customer assistance; Customer care; Customer support; Service marketing; Support service

Definition/Description

Customer service focuses on solving problems for the customers to the satisfactory level. It provides the customer with the right information at the right time through all stages of the consumer decision journey. Covering all stages from consideration to the purchase and finally forming the overall customer experience. Customer service covers many different stages of customer interaction with company, and all these stages create positive or negative customer experience with the company, product, or brand.

Customer service is the place where customer starts the conversation with the company. This momentum is crucial since when customer decides to spend its time to talk to the company, they expect the absolute dedication and final solution to any question, demand, and expectation they may have. Customer service is one of the most important points of differentiation and competitive advantage for the company. Customer service not only solves problems for the customers but also collects feedback and information about the company, products, and brands in order to improve on the successful sustainable interaction of company and customer.

Customer service covers three main aspects when dealing with the customer, and they are speed, solution, and trust.

Speed

Interaction with the customers must be prompt and fast. Customers have no time to lose, and

they expect the problem to be solved now. They dedicated their time to the company, product, and brand, and they need this time to be well spent. Thirty seven percent of consumers expect a response to social media questions and complaints within 24 h (Mazareanu 2019).

Solution

When it comes to the solution, customer service provides professional, punctual, and accurate solution to the problem expressing high level of knowledge and skills on the matter.

Trust

If above two steps are met at the end, well-executed customer service builds trust between the customer and the company. People buy from those they trust. It is hard to build trust and yet so easy to lose it.

Introduction

As long as there have been customers, there has been customer service (Delbos 2017). At the open market, customers have their own seller while there are many. What is so special about the one they chose? It is service, trust, experience, and emotional build in customer service. It is “face-to-face” experience. Customers need that human touch, the feeling of honesty and importance. When customers experience excellent service, they experience friendly, responsive, and empathetic reaction from companies, whether it is about answering a question, offering advice, or accepting the return of faulty merchandise. It is Buttle (2009) who writes about empathy and responsiveness and its connection to humans. Bitner (2018) further explains that the quality of customer service is essential to building customer relationships.

Customer service is becoming of great importance within companies in today's competitive environment. According to Gartner (Tom McCall 2015), nearly all companies surveyed by Gartner (89%) believe that customer experience will be their primary basis for competition. Many companies look at customer service from both sides,

from the customer's point of view and the company's point of view, and try to meet the two. The best companies are focusing on customer experience, the role that customer service plays in a company's competitiveness – as the direct link to greater customer intimacy, greater brand loyalty, and faster brand growth (Greenberg 2010).

Bitner (2018) points out that services are deeds, processes and performances provided and developed by one entity or person for another entity or person. It is not only about the process, it is also the people who are running the process, the organization around the process, where it all must be done to the absolute perfection. As stated in MacDonald (2020), delivering great customer service is not only about handling the request when it has been received; it's also about the follow-up, the speed, and the quality.

It is argued by Nextiva (2019) that customer service department did not exist decades ago, and today they are a large part of any successful business. In traditional approach customers communicated with companies through mail, phone, and more recently email. In the old days, writing a mail to the company puts a great effort from the customers to start a dialogue. Today, customers' expectations grew, and the power is in their hands. There are several main types of customer services. It is possible to reach companies by phone or email or to go on social medias. Customers can also check the FAQ (frequently asked questions) or forums. There are online communities where consumers help each other. Video help is growing, e.g., YouTube, where customers seek solutions, help, and answer to their questions and problems. There are quite a few customer service channels available: from phone support, email support, on-site to live chat support, social media support, FAQ, customer self-service, video support, to omnichannel support. They differ from each other, and thus some of them are more suitable for certain business types than others (Sienkiewicz 2019).

Companies try to ensure that customers will be happy with the interaction when they connect with their product, customer service, sales staff, or marketing materials (Maechler et al. 2016).

Key Issues

Blunt and Hill-Wilson (2013) pointed out that customers had tried to get their problems resolved through traditional customer service channels, but the satisfaction was not to the expected level. When customers are not satisfied, they share this information with others. Bad news travels fast. According to Phillip (2017), “fast” has been replaced by “warp speed,” as social media has enabled anything to become viral and remain a few clicks away for eternity. The study from SuperOffice (MacDonald 2020) found that:

1. 62% of companies did not respond to a customer service emails.
2. 90% of companies do not acknowledge or inform the customer that an email has been received.
3. 97% of companies do not send a follow up email to customers to see if they are satisfied with the response.
4. Only 20% of companies are able to answer questions in full on the first reply.
5. The average response time to handle a customer service request was 12 hours and 10 minutes.

Above numbers show the enormous opportunity in building the competitive advantage based on customer service. Today, 89% of companies compete primarily on the basis of customer experience up from just 36% in 2010 (Hyken, 2018). This is the new battlefield for the companies. This is the new market, new way of doing business and compete. They do not compete on brands only but more and more on service, in creating superior customer experience. Sometimes companies are detached from the reality. If they do not listen to the customers, they are driving to the wrong directions. Research from Bain & Company (2005) shows that 80% of companies believe they deliver “super experiences”; only 8% of customers agrees.

Customer service is the new brand. Every brand must be carefully and sustainably treated as the most important asset of the company.

Customer service and sustainability are linked together. As Rosen (n.d.) points out, customer

service performance that is not sustainable can seriously harm relationship with your customers because companies create expectations for customers that companies are in time unable to meet. The sustainability is built in interaction with the customers and through customer service. Schofield (2018) explains that to build sustainability, the priority must absolutely be customer satisfaction and loyalty.

Future Directions

In today's connected world, customers expect to receive service on their own terms – anytime, anywhere (Microsoft 2017). Customer service is to be done to “one.” We are all different and we all need different services. Technology of today and tomorrow enables companies to have a personal approach to every single customer. It is important to find the best ratio of technology and personal, human touch. That is why omnichannel customer support is important. Customers sometimes use emails first or live chats or social media support, but often they make a phone call to talk to a living person. Greenberg (2010) explains that customers want to deal with individual humans, but otherwise be left alone to craft a personal approach to their interactions with you in the way that fits their desires – not yours as the company.

Establishing a lasting relationship with consumers is based not only on giving them what they want or knowing them well but also on gaining their trust (Fenech et al. 2016). Alexa from Amazon and Google assistant are personal virtual assistants that customers can talk to. Customers can ask them different questions, seek solutions, and ask for more information, and they will get the answers. It is a whole new way of interaction. Virtual assistants have the “human” touch: they listen, they give feedback, and they ask for more information in order to be able to help. Virtual assistants are new decision-makers and influencers. For example, if you ask to fix a problem on your television, a virtual assistant can assist you but can also offer you a new television,

that is, by the reviews, better than the one you have at home and influence you to buy a new one. The more trust virtual assistants build with their customers, the more power they gain to influence customer behavior. Trust lies at the core of good customer service (our research found that 76% of people say trust is key to good customer service), and it has to be established before users can be expected to take part in deeper engagements (Mindshare 2013).

Consumers not only expect personalized products and services as standard, they are also embracing different ways of buying or enjoying products and services (Fenech et al. 2016). To be able to personalize service, companies must use new technologies such as artificial intelligence together with big data. Hermani (2016) estimates that by 2020, 85% of customer service interactions will be automated.

Summary

Customer service offers support to the customers, and they give the final solution to customer's needs and expectations. Customers hold the power today, and they want to feel important. Companies who understand this will create trust and loyalty with their customers. It is so easy to lose the customer, or competition can win it over just by providing better service that leads to the better experience. The report from Microsoft (Microsoft 2017) reveals that 96% of respondents say customer service is important in their choice of loyalty to a brand. Customer service has the direct implication to the business success. It is becoming a vital part of the future of your business.

As Robert Murdoch said: “Big will not beat small anymore. It will be the fast beating the slow” (Bannister and Barrie 1999).

Customer Support

► Customer Service

Customer Value Creation

Stefania Vignini

Department of Management, University of
Bologna, Bologna, Italy

Definition

The concept *customer value* has many meanings (Woodall 2003), but, from a marketing theory, two dominate: customer value refers to customers' perceptions of what they receive and in return for what they sacrifice (Zeithaml 1988). The creation of customer value has long been recognized as a central concept in marketing (Woodruff 1997) and the fundamental basis for all marketing activity (Holbrook 1994). There are two aspects to

customer value: desired value and perceived value (Woodruff 1997). Desired value refers to what a customer desires in a product or service. Perceived value is the benefit a customer believes he or she received from a product after it was purchased.

Anderson et al. (1997) define three kinds of customer value propositions: all benefits, favorable points of difference, and resonating focus. “All benefits” value propositions are based simply on listing the positive features and outcomes of buying and using the product or service.

A Customer Value Creation for Businesses

Value creation is the primary aim of any business entity. Creating value for customers helps sell products and services, while creating value for shareholders, in the form of increases in stock price, insures the future availability of investment capital to fund operations.

Creating customer value increases customer satisfaction and the customer experience. (The reverse is also true. A good customer experience will create value for a customer). Creating customer value (better benefits versus price) increases loyalty, market share, price, and efficiency and reduces errors.

Customer value creation is the most important and crucial part of every business. Being the important part, it is also a difficult part to be implemented in the business.

The executives should develop a clear strategy for creating customer value as this plays a very important role in determining the market share price of the company.

Customer value propositions are formulated by assessing the current market offerings, identifying what customers want, and then developing solutions that meet the market need for a product or service (Anderson et al. 1997). Figure 1 illustrates the customer value creation strategy; it is the author’s representation of the extant literature.

Shanker’s article examines the dimensions of customer value creation and provides a framework to help entrepreneurs, managers, and leaders of open-source projects create value.

A customer value proposition can be developed based on the points of value that an organization can create. In this respect, a customer value proposition must provide distinctive, measurable, and sustainable value (Anderson et al. 1997).

O’Cass and Ngo (2011) assert that a firm’s pre-emptive value-creation strategy is comprised of:

1. Performance value: This component is associated with the product attributes and the attributes’ performance. This relationship was also noted Woodruff (1997).
2. Pricing value: This component can refer to the fair price or the value price. The fair price refers to customers believing they are paying a fair price for a product or service; the value price refers to a price that justifies the benefits of purchasing a product.
3. Relationship value: This component refers to the firm’s efforts to create and deliver a hassle-free purchase and consumption experience.
4. Co-creation value: This component is added when customers find it beneficial to influence various parts of the business system to co-create or co-produce their own unique purchase and consumption experience.

Customer Value Creation, Fig.1 A firm’s value creation strategy (Shanker 2012)

According to Shastry (2018), knowing about what the customers want and working on the same may help you attract more customers. This can be done via surveys, polls, etc. It is important as you will be providing the customers exactly what they want.

It is very important that customer value creation is applicable in all the fields like business, service, education, education, etc. So, one should always focus on customer value creation as much as possible.

Identification of the customers as per various demographic and geographical aspects is very important to clearly understand what a customer will benefit from your product or service.

Understanding the need of customers and what your brand is offering to them is very important. A customer's benefit is calculated excluding the purchasing cost.

Customer value directly affects the reputation and profit of every company. So, planning and implementing the right strategy for achieving the same is very important.

The team should be clear in mind what they are going to focus in order to get connected with more and more customers and to get the best feedback from them.

The best way for customer value creation is the values you hold within your organization. The values like integrity, honesty, loyalty, etc.

According to Shastry these are best things to create a good customer value.

The above mentioned points were some of the necessary ways by which customer value can be created. So, after knowing the importance of customer value, one can benefit a lot if utilized effectively and to the fullest.

Creation of value for customers is a critical for marketers when developing new products and services or starting new businesses. The paper of Smith and Colgate presents new conceptual framework for marketers to ponder when

exploring ways to distinguish themselves, in the eyes of the customer, from others in the marketplace. This framework is built on the strengths of existing frameworks.

Data Protection

Kadir Atilla Tokar
Dokuz Eylul University, Izmir, Turkey

Synonyms

[Data care](#); [Information misuse](#); [Information protection](#); [Information security](#)

Definition

Data refer to the facts and concepts about unidentified entities. Data become information after processing by human and/or IT tools. Data protection is the implementation of administrative, technical, or physical measures to guard against unauthorized access to data. Today, it refers to the prevention of the misuse of individual data.

Introduction

The term data is derived from Latin term “datum,” which means “something given.” Generally we

use the term “data” in different contexts to refer to raw material, facts, or statistics gathered by a researcher for analysis. Data are aperspectual, ahistorical, acontextual, unstructured facts, or raw materials that record particular instances of reality. After being recorded and processed, they become a systematic and filtered form of data called information. In other words, “data are formalized representations of information, making it possible to process or communicate” (Campbell and Shin 2011). The possible characteristics of data are as follows:

- Randomly collected raw material about a condition, event, idea, or an entity.
- An unorganized form of simple text and numbers requiring processing to draw conclusions.
- The input language for a computer in contrast to information as the output language for humans.
- Based on observations and records rather than specific information.
- Data collected by the researcher may or may not be useful, whereas information is valuable and useful in the given context and readily available to the researcher for use.
- Data is gathered with irrelevant facts and figures that need to be eliminated during the transformation into information.
- Data does not depend on information whereas information is generated from and therefore always depends on data.

The computing environment is fast-growing. During 2016, an estimated 5.5 million new devices were connected every day, with an expected 50 billion connected devices by 2020 (Harkins 2012). Nearly any device with an IP address will be able to communicate – and also be attacked – over the Internet. Since the sheer volume of information is exploding, business has quickly realized the value of massive unstructured data. The new era gives companies “vast opportunities to collect information from multiple online sources, and analyze and sell it to others” (Harkins 2012). Use and misuse are both possible, as recently experienced with the Facebook and Cambridge Analytica scandal. Consequently, two important controversial issues affect societal development: personalization versus privacy. Personalization focuses on collecting, analyzing, and reselling information about individuals, which began with mass-mailing campaigns before becoming routine through web capabilities. Through technology, companies can now store ever more personal information without explaining why. Moreover, their methods to protect and the time they keep such data are unknown.

This development has made privacy an important issue because “businesses increasingly seek to create online experiences tailored to the needs of individual users” (Harkins 2012). Privacy is the right and choice of the individual to reveal information to others (Westin 1967). It is thus guaranteed only if individuals have necessary knowledge about the data collected from them (Foxman and Kilcoyne 1993). Businesses aim to personalize services and offer targeted advertising based on each individual’s income and preferences. There are therefore immense conflicting desires for personalization and privacy, which have led to stricter laws and regulations to protect the privacy of individuals in the name of data protection. Data protection is “the implementation of administrative, technical, or physical measures to guard against the unauthorized access to data” (Toker 2015). It includes the ethical dilemmas, concerns, controversies, regulation of data misuse, and the legal and ethical precautions to avoid it, which we face as a twenty-first-century threat.

All countries link the free flow of information and data protection through a legal framework. On the one hand, individual privacy is challenged by widespread data collection and communication tools. On the other hand, the growing information economy depends on freedom for businesses to gather and distribute information. Although data protection is a legal issue between government and business, there is also a link between business ethics and the protection of customer data through the emerging CSR logic.

History of Data Protection

The protection of personal data is the right to be left alone, which was first named by Samuel Warren and Louis Brandeis more than a century ago. Privacy is considered a natural and key aspect of individual freedom that refers to the limits of an individual’s personal sphere. In contrast, the demand for transparency in business life has become a serious pressure in the globalized age.

According to Toker (2013), “The growing use of computers to store information about individuals has led many countries to pass laws in order to protect the privacy” and unauthorized access of others. After Germany passed the first data protection law in 1970, “in 1973 and 1980, one-third of the OECD’s 30 member countries enacted legislation intended to protect individuals against abuse of data related to them and to give individuals the right of access to data with a view to checking their accuracy and appropriateness” (Toker 2013).

In the United States, data collection in electronic commerce is still unregulated, except in health care, financial services, and children’s Internet use (Fernback and Papacharissi 2007). In contrast, privacy is more strictly protected in Europe (Baumer et al. 2004), which has proven to be a hurdle for US technology companies like Google operating there. Recently, Spain fined Facebook over one million euros for a privacy breach while the European Union (EU) fined the same company 110 million euros for not to link gathered data to WhatsApp accounts. The EU Data Protection Directive was adopted in 1995, whereby the EU Commission emphasized the

direct link between data protection and fundamental rights. In 2018, the EU introduced the General Data Protection Regulation (GDPR) to strictly protect data privacy, including medical records, bank statements, and Internet searches. This increases confidentiality for citizens while supporting their right to better control their personal information. GDPR gives people “a right to receive clear and understandable information about who is processing personal data, what data they are processing and why they are processing it” (EU GDPR 2018). The law gives individuals the right to transfer personal data to another service provider or ask a company to delete personal data to ensure the right “to be forgotten.” This recent law has greatly affected privacy practices of companies worldwide. It is also shaping corporate responsibility programs.

Recent data protection violations involving Facebook and Cambridge Analytica provide an important example to show that the data has become “the new corporate currency” of the information age. Therefore, data protection is an important challenge for the twenty-first century. Despite Europe’s legislative efforts, data privacy violations have occurred in DeutscheBank in Germany and T-Mobile in the UK. The main problem is that technology is changing too fast for privacy legislation to keep up. Incorporating data responsibility within the Corporate Social Responsibility (CSR) framework could provide an effective solution.

In sum, data protection is being elevated to a constitutional right. Although data protection refers to the prevention of the misuse of data, particularly information about individual people, and is mostly linked to laws and regulations, increasing societal pressure and public awareness has also forced companies to associate data protection with CSR in their business ethic approach and actions.

Summary

In simple terms, data is unorganized information or input, which is used to generate output, known as information. Data refer to facts and descriptions from which information can be extracted. Apps,

social media, e-commerce platforms, and consumer devices like mobile phones, commercial cameras, and even cars generate terabytes of data about individuals and the environment, which testifies that we live in an era of Big Data. Through such valuable data, companies know what consumers want even before consumers realize they want it. This new era should bring data responsibility in terms of data collaboration or ways for companies to share proprietary data for the public good. This suggests a new type of CSR for the twenty-first century.

Currently, many companies gather and store data for marketing and other purposes (Matwyslyn 2010). Companies face two major requirements to support a socially responsible and secure society: information transparency and data protection. As people depend more on technology and their lives go increasingly online, the protection of privacy as a human right is becoming more important than ever. This gives companies a huge responsibility to safeguard the privacy of the personal data which they collect.

Debt Relief Systems: Equitable Allocation

Xiaojing Wang¹ and Anne Marie Ward²

¹Ulster University, Newtownabbey, UK

²Ulster Business School, Ulster University, Newtownabbey, UK

Synonyms

[Bankruptcy regulation](#); [Household bankruptcy](#); [Insolvency regulation](#); [Overindebtedness regulation](#); [Personal bankruptcy](#)

Definition

Personal debt relief systems are established by governments to manage overindebtedness problems within society. Personal debt relief systems are also referred to as personal insolvency and personal bankruptcy systems. Personal debt relief systems apply to natural persons and include self-employed individuals and individuals who are not self-employed. There is no consistent approach to personal debt relief; some countries enable a quick exit from the burden of debt, for example, the United States, whereas in other countries, a prolonged exit is favored, for example, full debt relief typically takes up to 3 years in Germany. This entry outlines the importance of debt relief systems to national sustainable development. We discuss personal debt relief systems in different countries, including the United States, England and Wales, Germany, and Ireland. The systems range from “straight” debt relief, which provides an immediate exit from prior debts, and debt consolidation, which strategically packages an individual’s debt into a consolidated loan and arranges repayment by the individual over a period of time depending on their disposable income. Finally, we conclude by examining the function of debt relief systems and how they can support sustainable development within a country.

The Importance of Debt Relief Systems to National Sustainability

Financial market deregulation in Europe in the 1980s resulted in increased competition between financial institutions, a wider range of consumer products, and easier access to credit. This resulted in increased personal debt levels. According to a study by Eurofound (2013), about 44% of the population in the European Union (EU) have substantial debt levels and many of these experience financial difficulties. The problem varies across countries within the EU, but nations with the greatest levels of personal debt include France (debt levels exceeded net disposable income at

106% in 2014), Germany (debt amounted to 94% of net disposable income in 2014), and Italy (debt amounted to 90% of net disposable income in 2014) (OECD 2017). The increase in consumer debt levels is seen as a cause for concern by global policymakers due to perceived links between consumer debt levels and national social and economic development. In particular, personal overindebtedness problems are deemed to be related to psychological and sociological consequences such as stress and social exclusion (Athreya 2004; Schicks 2013) and consumer confidence. On the one hand, consumer confidence affects demand and hence the economic outlook within a country. On the other hand, consumer confidence is related to the income capacity of an individual. When individual consumers face overindebtedness and possible bankruptcy in their future, their income productivity can decrease as a result of lost confidence and social and financial exclusion. Therefore, if sufficient numbers of the population are overindebted, the social and economic impact can significantly impact on a nation's sustainable development. Debt relief systems, which provide an exit for overindebted and bankrupt individuals, serve to reduce the negative impact of personal bankruptcy and hence contribute to a nation's sustainable development.

Personal Insolvency in Different Countries

Unlike business insolvency, which has existed in many countries for many years, personal debt relief systems have typically been implemented by governments since the late 1970s. A wave of financial deregulation in the 1980s led to increases in the availability of credit and a consequential increase in the number of overindebted individuals. National policymakers acted by introducing or reforming personal insolvency laws. As a result, country-specific approaches to the resolution of overindebtedness emerged. The United States was the first country to introduce personal insolvency regulation, allowing individuals to file for bankruptcy, under the US Bankruptcy Code in

1978. It was then followed by Denmark in 1984 and the United Kingdom (England and Wales) in 1986 (Ramsay 2017). The personal debt relief systems for the United States and some European countries are now outlined in brief.

United States: In the United States, individuals have two avenues for exiting from their current untenable financial position. These avenues are covered by two “chapters” in the Bankruptcy Code. Individuals can either file for bankruptcy under “Chapter 7” or “Chapter 13.” A Chapter 7 filing provides a quick exit for the individual. Under Chapter 7, individuals have to sell all their nonexempt assets. The funds received are used to repay their debt owing. The level of exempt assets is determined by state government in the United States. All other debts are discharged. Under a Chapter 13 filing, individuals do not get an immediate discharge from their historical debts. A Chapter 13 filing leads to a repayment plan for individuals with a regular income. It is also known as the “wage earner’s plan” (US Courts 2019). Under this filing, individuals sign up to repay their debts over a period of between 3 and 5 years. The individuals usually get to keep their assets. Their debts are not discharged. They are consolidated into a manageable debt plan that is administered by a Chapter 13 trustee. The individual makes one payment to the trustee, who distributes the funds to the relevant creditors.

There was much controversy and lobbying against Chapter 7 bankruptcy filings by creditors who argued that such an easy exit promotes dysfunctional consumption behavior by unethical individuals to the detriment of creditors. As a result, in 2005, the Bankruptcy Abuse Prevention and Consumer Act (BAPCA) came into effect to avoid the abuse of Chapter 7 bankruptcy filings by individuals. Now a “means test” for individuals is required before they are eligible for bankruptcy under Chapter 7. Any individual who has a monthly income that is greater than the state median has to be subjected to the means test to determine whether or not they qualify for a Chapter 7 filing. The means test includes evaluating their income over the previous 5 years to determine if their spending could be considered to be abusive (excessive). If it

is considered to be abusive, then their application will be dismissed or transferred for consideration under a Chapter 13 filing.

There are a variety of approaches to personal insolvency in European countries; however, most involve debt restructure and a repayment plan for individuals. The systems in England and Wales, Germany, and Ireland are now explained in brief.

England and Wales: The legislation covering insolvency in England and Wales is the Insolvency Act 1986. This legislation has been modified over time. The most recent change was the establishment in 2002 of the Enterprise Act. Under this Act an individual can apply for a Debt Relief Order (DRO) or Bankruptcy Order if he/she can't repay his/her debt. Individuals with debt under £20,000, who don't have much spare income and don't have their own home, are eligible to apply for a DRO. DROs enable eligible applicants to get a discharge from all their debts after a 12-month period. Under the Bankruptcy Order, individuals have to sell their assets to repay their debts, and all remaining debts are discharged after 12-month period (UK Government 2019).

Germany: In Germany, the first personal insolvency law, the Insolvency Act, *Insolvenzordnung-InsO*, came into effect in 1999 (König 2016). Under the Act, when individuals file for bankruptcy, they are required to first seek an out-of-court settlement with their creditors. Insolvency proceedings only arise if no agreement is reached. At the outset individuals are required to liquidate their assets to repay their creditors. In addition, the individual has to sign up to a period of 6 years "good conduct" after which any remaining debt will be discharged. However, this arrangement was deemed to have negative consequences for the individual and society; therefore, in 2014, an amendment to the Insolvency Act came into effect, which shortened the repayment period for individuals. Now individuals who repay at least 35% of all their debt balances can get their remaining debt discharged after 3 years (König 2016). This more lenient approach is deemed to be better for Germany's sustainable development and should improve societal welfare.

Ireland: In Ireland, policymakers have also moved toward quicker debt relief for individuals.

Historically, Irish legislation on personal insolvency was strict relative to other European countries such as Germany. Before 2012, individuals who filed for bankruptcy had to repay their creditors for a period of up to 12 years before they were able to obtain discharge from any remaining debts (Gerhardt 2009). As a result, most individuals sought arrangements with their creditors, rather than filing for bankruptcy. As a consequence of this punitive system, the bankruptcy rate in Ireland was low, with only five persons declared bankrupt and ten persons being declared exempt from their debt obligations in 2007. However, this system could not continue. The negative social impact of the financial crisis was particularly acute in Ireland. In the period before the financial crisis, the Irish economy experienced exceptional growth. This period became known as "Celtic Tiger." The buoyant economic environment resulted in a boom in the housing market and soaring personal debt. An immediate consequence of the financial crisis was a collapse of the housing market and credit rationing by finance providers. Suddenly, many individuals found that their properties were in negative equity, as the debt owed on their properties exceeded the new lower value of their properties. Their problems were compounded by a contraction in the job market, wage reductions, or pay freezes. The government had to act to cushion the societal impact of the downturn of the economic crisis and to enable individuals to start again. A review the insolvency rules in favor of shortening the discharge period to ease the burden on individuals was commissioned. As a result of this review, the new Personal Insolvency Act 2012 was enacted. The Act reduced the "good conduct" period from a maximum of 12 years to 3 years. This was further reduced to 1 year on the 29 January 2016.

It can be seen from these country-specific examples that the general consensus by policymakers is that personal bankruptcy is bad for society and the economy and that a fresh start is best for both the individual and the nation's sustainable development. Hence most are moving to shorter-term debt relief systems that offer a new start. However, there is debate about whether this approach is appropriate. This is now discussed.

Apportioning the Blame for Insolvency

Policymakers across countries are united in the view that personal debt relief systems are an important tool for managing social and economic problems. However, differences in debt relief design result from differences in policymakers' views in respect of who contributes most to the insolvency loss – the individual or the creditor. On the one hand, it could be argued that the loss arose because the creditor provided credit too freely that their credit assessment procedures should have averted the problem at the outset. If this is the view, the credit provider is deemed to have contributed most to the insolvency problem, and policymakers are more likely to design “consumer-friendly” debt relief systems that enable the consumer to exit quickly, and as a result, the creditor bears most of the burden of the loss. On the other hand, it could be argued that the loss arose because the consumer behaved unethically, by borrowing more than they could afford to pay back. If this is the view, then “creditor-friendly” debt relief systems are more likely to be implemented, requiring a greater repayment commitment from consumers.

Debt Relief Systems as a Policy Tool

In the United States, easier debt relief for an individual's overindebtedness is part of the government's toolkit, used to alleviate those who are least well off in society. In this respect, the US debt relief system is considered a form of insurance that becomes effective when personal financial hardship is not subsidized by welfare support and is most likely to arise when the individual sources debt to pay for health care. The belief is that individuals who get their debt discharged under Chapter 7 can have a “fresh start” quickly and regain their capital productivity, thus reducing costs to families, communities, and financial markets. Welfare systems are not as supportive in the United States as in many European countries, and hence a “consumer-friendly” approach is adopted. The difference with the systems evident in European countries is that, while a fresh start is

promoted, there is more emphasis on providing guidance. This usually involves financial education, debt reorganization, and debt restructure. The aim is to encourage responsible borrowing in the future.

Summary

Debt relief systems are in place so that individuals can discharge debt that they can no longer repay. During the process, the creditors' right to get their money back is sometimes less protected. As a result, an equitable allocation of cost among interested parties in bankruptcy proceedings should be maintained. Debt relief systems should not only provide an exit mechanism for overindebted individuals but should also ensure that both individuals and creditors bear their proportion of the costs resulting from bankruptcy. An equitable allocation encourages both responsible leading and borrowing and encouraging productivity from individuals. By providing an exit mechanism for overindebted individuals, debt relief systems help reduce the negative impact of household debt on a nation's sustainable development by easing its associated social and economic costs.

Decade of Education for Sustainable Development

[Sustainable development](#)

Definition/Description

Having its origins in the education chapter of Agenda 21 of the 1992 Earth Summit the United Nations Decade of Education for Sustainable Development (DESD) ran from 2005 to 2014 (Unesco, N.D.). Addressing sustainable development through education served to raise awareness of the issues, broaden the scope of the message, and to educate to deliver transformation in thinking, policy, and practice.

Introduction

Working with educational partners to develop, trial, and scale up ESD provision the decade of work has delivered long-term results (Unesco, n.d.). The ultimate purpose of the change in thinking about sustainable development was to deliver a change in policy and practice (Borys, 2010; Tilbury, 2011). Identifying ways in which opportunities for learning can advance sustainable development and how these can be incorporated in and beyond the formal curriculum were part of the program aims (Tilbury, 2011). Real-world change can be brought about through education and ESD seeks to transform learning and the process of learning (Jorrit et al., 2020). The DESD recognized that sustainable development did not always have the presence it deserved in different phases of education, be that formal or informal and sought to address that by a whole systems approach. The United Nations Sustainable Development Goals (SDGs) provide the context and background to ESD and help inform the work of the program. The DESD has influenced work on the environment, society (culture), and the economy. Involving people, engaging communities, and using learning to deliver more sustainable futures helped mark the DESD as distinctive in its offer and approach. Its international approach also distinguished this program from the sole country approach. The international dimension allowed for learning and findings to be shared openly and transparently and from this, use of good practice could be more widely adopted. Government commitment to the DESD helped drive and motivate action and deliver the goal of new approaches to education for sustainable development. International cooperation and the buying into shared values helps create new opportunities that would not otherwise have arisen had the DESD not occurred. The 2009 Bonn Declaration was born of the DESD and it called for increased awareness of sustainability, that this should be driven by government and that quality education should be a priority. Encouraging dialogue through contact networks and including a range of stakeholders helps to promote a

democratic ideal and an inclusive approach to ESD helps to widen and potentially deepen the learning and the debate. Community engagement in ESD validates the approach and work being done. This socially inclusive approach and advancing the democratic ideal serve to address some aspects of the SDGs. Learning about ESD is formal and informal and is seen to occur not just in the classroom but beyond it, for example in the community. Learning involves being able ask questions that show some critical awareness of issues around ESD. Critical reflective thinking is built into and is a desired outcome of the overall ESD pedagogy. Educating for ESD should adopt an interactive approach and one that challenges established and often taken for granted positions. Active learning that has a theoretical underpinning but that is applied and practice-based helps embed knowledge, values, and skills. In a formal classroom environment suitable approaches to ESD learning might include case studies, role play, or among other things group discussions and debates. There is no “one right way” to deliver ESD and the approaches taken will vary according to the nature of the students, their level of knowledge, and the intended purpose or planned outcome of the learning. Story-telling and acting are good for educating about ESD in a supportive and non-threatening learning environment. Learning about ESD takes place throughout different phases of education and runs throughout students’ time in education. Undoubtedly, teachers play a prominent part in ESD and their support is critical to the delivery of successful outcomes. Education, in the myriad forms it can take, shapes and influences sustainable development. Being able to contribute to, participate in, and to engage with advancing sustainable development in thought, word, and deed is something all citizens should feel comfortable and confident doing. The voice of citizens who may previously have been less vocal on ESD will have had the opportunity and potential to be raised as a result of the many educational interventions made during the decade of work. Delivering change in practice requires a change of heart and mind and this is something DESD sought to do with purpose and gusto.

Complex challenges around the most appropriate ways for education to deliver sustainable development that could secure stakeholder agreement and consent was something addressed at the outset and throughout the life of the program. Challenging, questioning and reflecting were used to learn and develop and were built into the DESD to allow for deep learning to take place.

Summary

A sustainable future can, in part, be realized through ESD and the work done in the DESD served as a stimulus for discussion, debate, action, and progress (Unesco, [n.d.](#)). Today, ESD is widely recognized and a legitimate area of educational endeavor. ESD knowledge, skills, and indeed experiences are co-created through the process of learning and this serves to empower, enrich and enable learners. The DESD was a value adding program that delivered long term results.

Laure et al. (2016) undertook an 18-country study of ESD and they found that school-based primary and secondary phases of education reported improved quality provision, and a transformed curriculum. Subject knowledge and material content had a strengthened sustainability focus. ESD pedagogies contribute to new skills and knowledge that help deliver an approach to the economy and society that is more sustainable (Laure et al., 2016). ESD pedagogy is proven to be effective, and Tilbury (2011) has promoted this approach that emphasizes theory rich, applied learning, and problem solving. The future for ESD was enhanced by the work done during the decade that the program ran. This collective, program partnership approach led from the “top” and achieved buy-in from the “bottom” and the result was an increased shared ownership of the problems of ESD, and the potential educational solutions. A more sustainable tomorrow was partly the result of actions of past (DESD) and activities of the present (ESD). No one singular approach can “solve” the multiple challenges associated with sustainable development but educating for this now, as a result of DESD, has a more prominent

profile. DESD was only the start of an educational conversation and this is on-going and more pressing as the need find new ways to address sustainable development challenges is likely to increase as demands to address, for example, the climate emergency grow. New interventions for ESD need to be encouraged at a local level but they also need policy actions to be led by government.

[Conceptualization of CSR; CSR meaning](#)

Description

Corporate social responsibility (CSR), in its fundamental meaning, refers to corporate practices that go beyond legal mandates on “trading, health and safety, human rights, consumer and environmental protection and reporting” (Katsoulakos and Katsoulacos 2007, p. 361). The literature is not unanimous about CSR definition, its scope, and principles (Garriga and Melé 2004; Marrewijk 2003) and, finally, as to whether firms

have any responsibility toward other stakeholders beside shareholders (Friedman 1970). “The definition of CSR is both complex and complicated” (Sheehy 2015, p. 625), what makes the understanding of the phenomenon difficult for academics, managers, politicians and citizens. While its complexity arises from the multifaceted nature of environmental, social, and economic problems, the complication comes from different agendas and interests of parties (including scholars, governments, managers, employees, NGOs) involved in the definitional effort.

Nevertheless, despite the complexity of the CSR phenomenon, the need to define it is growing. These definitional and conceptual inconsistencies hamper both academic debate, as well as corporate implementation (Goebbels 2002). The broad scope of CSR decreases its relevance to organizations and researchers (Marrewijk 2003). The precise CSR definition is the more desirable considering the fact that responsible and irresponsible corporate behavior have legal and economic consequences (Sheehy 2015).

Introduction

CSR is viewed as a building block for modern literature on business and society relationship. Although it started to be explored already in 1950s (Carroll 1999), it is still one of the most controversial and ambiguous concepts in management. CSR is described as knowledge “in a continuing state of emergence (...) not characterized by the domination of a particular theoretical approach, assumptions and method” (Lockett et al. 2006, p. 133). The CSR research has been largely developed in silos making it impossible to formulate any coherent theory. CSR has been defined from different academic lenses by scholars representing economics, business, law, and political sciences (Sheehy 2015). Thus, the understanding of the term ranges from profit sacrificing activity (Doane 2005; Friedman 1970; Karnani 2011a, b), marketing tool (Fleming and Jones 2013), business strategy aimed at creation of shared value (Porter and Kramer 2011) to global business norm (Muhle 2011).

Scholars started to point to the problems with defining CSR already in 1960s. “The phrase corporate social responsibility has been used in so many different contexts that it has lost all meaning” (Sethi 1975, p. 58), becoming “a nebulous idea” (Davis 1960). Over the last five decades, the rise of alternative concepts like CSR 2.0, corporate citizenship, corporate sustainability, or creating shared value (CSV) has only increased this definitional ambiguity.

Early Definitions

In the initial definition introduced by Bowen (1953 as cited in Carroll 1999), CSR was understood as “the obligations of businessmen to pursue those policies, to make those decisions, or to follow those lines of action which are desirable in terms of the objectives and values of our society” (p. 6). This institutional perspective on businessmen’s social responsibility provided a fertile ground for further academic discussion on the nature of CSR (Gond and Moon 2011).

In the 1960s, the literature on CSR expanded (Carroll 1999). One of the most influential contributors to the understanding of CSR was Davis (1960), who defined the term as “businessmen’s decisions and actions taken for reasons at least partially beyond the firm’s direct economic or technical interest” (p. 70). According to Davis (1960), “social responsibilities of businessmen need to be commensurate with their social power” (p. 71). If they fail to fulfill their obligations toward society, “other groups eventually will step in to assume those responsibilities and the power that goes with them” (Davis 1973, p. 314) – the rule known as “The Iron Law of Responsibility.”. Additionally, Davis (1960) was one of the first to point that some of the CSR activities can be justified as having potential positive impact on the firm’s performance in the long run; however, this relationship is “problematic” (p. 70).

Later McGuire (1963) pointed out that corporations have responsibilities that extend beyond economic and legal obligations. This was also highlighted by Davis (1973), who argued “that the social responsibility begins where the law

ends” (p. 313). The voluntary nature of CSR, as opposed to coercive, has been carried forward into many later definitions, including those presented by Walton (1967), Sethi (1975), Jones (1980), McWilliams and Siegel (2001), and the European Commission (2011).

In the 1970s CSR definitions not only proliferated but also became more specific (Carroll 1999). An important contribution came from the Committee for Economic Development (CED). CED’s basic assumption of CSR was that “business functions by public consent and its basic purpose is to serve constructively the needs of society – to the satisfaction of society” (CED 1971). The Committee presented three concentric circles of responsibility: (1) the inner circle – basic responsibilities for the efficient execution of the economic function; (2) the intermediate circle – responsibility to exercise the economic function with respect to social and environmental issues; (3) the outer circle – responsibility for improving the social environment.

A more instrumental view on CSR was presented by Eells and Walton (1974 as cited in Carroll 1999), who stated that “corporate social responsibility represents a concern with the needs and goals of society which goes beyond the merely economic” (p. 247). The authors elaborated that since the business system can only survive in an effectively functioning free society, CSR aims at improving social welfare.

According to Carroll (1979), CSR encompasses firm’s economic responsibility to investors and consumers, legal responsibility to the government, ethical responsibility to society, and discretionary (put differently, philanthropic or voluntary) responsibility to the community. Later, these categories were depicted in a form of pyramid with economic responsibility as the base (Carroll 1991). The author emphasized that the definition of CSR in order to be complete needs to encompass all kinds of responsibilities that a business has toward society and that also includes economic and legal categories. In the same time, he argued that managers need to take all of these responsibilities into consideration at all times.

Alternative Concepts

Gond and Moon (2011) described CSR as “chameleon concept” that kept changing its form, as several authors proposed alternative concepts. “Transformations of CSR occur not only at the skin level – with a change of concept (...) – but the CSR animal is also subject to multiple intra-cutaneous changes – the same label or acronym being transformed and redefined over time” (p. 12). Garriga and Melé (2004) proposed a fourfold classification of CSR theories and related approaches: (1) instrumental theories that view corporate social and environmental practices as means to achieve business goals (e.g., creating shared value); (2) political theories, which focus on the corporate responsibility stemming from the power that modern corporations hold in society (e.g., corporate citizenship); (3) integrative theories that focus on social demands toward firms and their approach to satisfying them (e.g., stakeholder theory or corporate social performance); and (4) ethical theories, based on ethical responsibilities of firms toward society (e.g., normative stakeholder theory, sustainable development). In practice, each CSR theory can be described with its assumptions in regard to four dimensions: profits, political performance, social demands, and ethical values.

Some of the most cited alternative concepts to CSR are presented in the following sections.

Corporate Social Responsiveness (CSR2)

“Corporate social responsiveness refers to the capacity of a corporation to respond to social pressures” (Frederick 1994, p. 247). CSR2 represents a transition from philosophical-ethical concept of corporate social responsibility (CSR1) that, as Frederick (1994) argues, was abstract and elusive, to action-oriented managerial approach focused on making organizations more responsive to forces from their environment. Social responsiveness can range on a continuum from reaction through defense and accommodation, to proaction (Carroll 1979).

Corporate Social Performance (CSP)

CSP is a three-dimensional model that incorporates the interaction between principles of CSR, processes of social responsiveness and outcomes of corporate behavior (Carroll 1979; Wartick and Cochran 1985; Wood 1991). In the final version of CSP model presented by Wood (1991), principles of CSR included Carroll's four categories of corporate responsibilities divided into three levels: (1) institutional – firm's generic obligation related with legitimacy granted by the society; (2) organizational – firm-specific responsibilities for outcomes of particular actions; (3) individual – managerial discretion. Environmental assessment, stakeholder management, and issues management were identified as processes of social responsiveness (Wood 1991). Finally, outcomes of corporate behavior encompassed not only policies, as proposed by Wartick and Cochran (1985), but also social impacts and programs (Wood 1991).

For some scholars CSP is simply a measure of CSR (McWilliams and Siegel 2000).

Stakeholder Theory

Stakeholder theory, popularized by Freeman in the 1980s (1984), assumes that a firm is a constellation of cooperative and competitive interests possessing intrinsic value (Donaldson and Preston 1995). With this assumption managers must formulate and implement strategies that satisfy all stakeholders, i.e., groups or individuals who are affected by or can affect company's strategies (Freeman and McVea 2001). Stakeholder theory is viewed as a complementary body of literature that offers operationalization of CSR (Matten et al. 2003). Although stakeholder management cannot be understood as a synonym to CSR, formulation and implementation of CSR strategy requires stakeholder dialogue and engagement (Greenwood 2007). Stakeholder management allows identification of specific groups, persons, and material issues a company should consider in its CSR activities (Carroll 1991).

Corporate Citizenship (CC)

According to the CC concept, a company is viewed as a rightful member of society with

particular rights and responsibilities (Matten et al. 2003). The literature provides three approaches to understand CC: (1) as a synonym for discretionary CSR, i.e., voluntary activities in the area of corporate philanthropy; (2) as a synonym for CSR; (3) as a corporate administration of citizenship rights in those areas, where governments fail to do so (ibidem).

Corporate Societal Responsibility

Andriof and McIntosh (2001) proposed the concept of corporate societal responsibility to address the limited interpretation of the term "social responsibility." While in Continental European cultures and languages "social responsibility" applies merely to social welfare issues, "societal responsibility" covers all dimensions of corporate impact on society.

Corporate Societal Accountability (CSA)

CSA, proposed by Goebbels (2002) as an alternative term for CSR, replaces the word "responsibility" with "accountability" in order to avoid similar problems as those related with the interpretation of the word "social."

Corporate Sustainability (CS)

The origins of CS are to be found in the concept of sustainable development, i.e., development that meets the needs of the present without compromising the ability of future generations to meet their own needs (UN 1987). CS can be understood as business contribution toward sustainable economies and society. Although traditional understanding of CS has been biased toward corporate environmental activities, recent research shows increasing interest in integrating social as well as economic aspects into this concept (Marrewijk 2003). As such, CS is inseparably linked with the triple bottom line (TBL) concept (Visser 2007) that introduces new approach to organizational performance measurement combining traditional financial bottom line with social and environmental performance (Elkington 1997).

CS, in its broad meaning that includes all three dimensions of sustainable development, is often

used as a synonym for CSR (Marrewijk and Werre 2003). However, Marrewijk (2003) calls to consider these two terms separately: CSR as a concept focused more on transparency, stakeholders dialogue, and reporting, and CS as an idea combining value creation with environmental and human capital management.

Corporate Sustainability and Responsibility 2.0 (CSR 2.0)

CSR 2.0 is a systemic approach to business and society relationship that involves product, process, and business model innovation as well as lobbying for progressive national and international policies. As such CSR 2.0 has potential to address the root causes of business present unsustainability and irresponsibility (Visser 2012).

Creating Shared Value (CSV)

Finally, CSV focuses on the integration of social and environmental issues with core business strategy and competitive advantage. Porter and Kramer (2011), who were the first to propose the idea of shared value, suggest that social needs can also define markets and become a source of innovation. By addressing social and environmental problems, companies can minimize internal costs and operational risks as well as identify new business opportunities.

Altruistic Versus Strategic Definition

In the literature there has been an ongoing debate whether CSR should be defined within altruistic or strategic approach. Within the first CSR is understood as “situations where the firm goes beyond compliance and engages in actions that appear to further some social good, beyond the interests of the firm and that which is required by law” (McWilliams et al. 2006). It is manager’s motivation that allows to differentiate between real, altruistic CSR and strategic CSR understood as a mere profit maximization strategy (Baron 2001). Involving in social responsibility firms should accept that costs of these activities may not imply any direct measurable economic returns

(Walton 1967). However, already in the 1970s authors pointed that business decisions may be motivated not by single, but multiple motives. Thus, distinguishing corporate social activities motivated purely by the desire to increase profit from those purely altruistic is difficult, if not impossible (Carroll 1999).

The alternative, strategic approach, popularized by Drucker (1984), Lantos (2002), Husted and Allen (2007), and Porter and Kramer (2011), just to name few authors, is based on the win-win assumption about business and society relations. It implies that a firm voluntarily invests in CSR, but designs a strategy so as to appropriate additional business benefits (Husted and Salazar 2006).

Toward Definitional Integration

One of the integrative definitions of CSR has been proposed by the European Commission (2011), which views it as a voluntary strategy integrating social, ethical, and environmental concerns with company’s core business activities in close cooperation with stakeholders. CSR aims at maximizing shared value creation for shareholders and other stakeholders, as well as prevention of negative impacts of business operations. With its definition, the European Commission stresses the importance of a comprehensive approach to CSR that covers all business processes. It builds on classical CSR definitions, including the Carroll’s categories of responsibilities and CED’s responsibility circles, and integrates them with alternative concepts that have been proposed over the last six decades, including CSV and stakeholder theory.

Another attempt to end the definitional ambiguity related to CSR was made by the International Organization of Standardization (ISO). ISO-26000 (ISO 2013), an international standard of social responsibility introduced in 2010, defines CSR as “responsibility of an organization for the impacts of its decisions and activities on society and the environment, through transparent and ethical behavior that: (1) contributes to sustainable development, including health and the

welfare of society; (2) takes into account the expectations of stakeholders; (3) is in compliance with applicable law and consistent with international norms of behavior; (4) is integrated throughout the organization and practiced in its relationships.” The standard identifies seven interdependent subjects that define the scope of social responsibility: (1) Organizational governance; (2) Human rights; (3) Labor practices; (4) The environment; (5) Fair operating practices; (6) Consumer issues; (7) Community involvement and development.

Summary

Despite the lack of universal definition of CSR, its conceptualizations available in the literature are predominantly congruent, as they consistently refer to the same five dimensions (Dahlsrud 2008):

1. Economic – CSR is described in terms of a business operation and encompasses socio-economic and financial aspects.
2. Social – CSR deals with issues related to business and society relationship.
3. Environmental – CSR deals with issues related to the natural environment.
4. Voluntariness – while CSR activities go beyond legal mandates, regulations specify the minimum socially acceptable level of corporate responsibility.
5. Stakeholder – the optimal, firm-specific level of responsibility is determined by the relationship with stakeholders.

Therefore, as Dahlsrud (2008) argues, it is not the lack of one universally accepted definition that is problematic, but the fact that those available fail to present any guidance on how to manage CSR issues.

Deforestation

Antonio Castrofino

Unitelma Sapienza University, Rome, Italy

[Forest degradation](#)

Definition

The forest is a collection of tall trees, higher than 5 meters, that spread over a large area of land, more than 0.5 hectares, and are part of a specific biome. Forests cover a third of the planet Earth, approximately 4.06 billion hectares (FAO 2020), and are essential for the production of oxygen and for the reabsorption of CO₂ from the atmosphere. Deforestation is the process of destruction or thinning of forest vegetation carried out by human activities, driven by economic interest. This destruction exacerbates the effects of climate change in many areas such as the loss of biodiversity and ecosystem services, soil organic matter, the increased risk of landslides and floods, the increase in temperature and drought as well as soil erosion. In addition, millions of individuals live near forests and depend on them for their survival. Their destruction, therefore, entails a very high risk of poverty and important socio-economic problems. In addition to the activities of the wood industries (paper, furniture, construction, and energy), food multinationals (large monoculture plantations and intensive farming), local farmers (e.g., agricultural method of slash and burn), another factor that moves toward deforestation is the increase of the population and the consequent need for more spaces and infrastructures. In many territories, economic interests have also pushed criminals over time to organize themselves to circumvent the laws protecting forests.

Introduction

Forests are the green lungs of the planet. They are custodians of biodiversity and allow the reabsorption of climate-changing gases thanks to the chlorophyll photosynthesis of plants and through the carbon cycle. Without plants and chlorophyll photosynthesis, it would be difficult to imagine life on our planet. Forests provide ecosystem services that can be summarized in life support, provisioning, regulation and cultural values (MA 2005). Over the centuries, however, human activities have greatly transformed the appearance of forests all over the world, reducing their number and size, reducing “virgin” forests (i.e., forests that have not undergone any human contamination), due to the need to expand their settlements and for reasons of exploitation of resources. The FAO, Food and Agriculture Organization of the United Nations, in the report “The Global Forest Resources Assessment,” estimates that in the period 2015–2020, 10 hectares of forests per year disappeared due to deforestation (FAO 2020).

To date, these activities, however, show all their danger since, deforestation and the forest thinning, leaving space for land exploitation activities lead in a short time to important changes in the water cycle and soil fertility, increasing the risk of drying up with subsequent soil erosion. In this dramatic risk situation is the biodiversity of the flora and fauna preserved within the forests. Furthermore, fires, often started by human hands, destroy plants and reduce the sequestration of climate-altering gases and evapotranspiration.

Forests, therefore, are essential for maintaining global temperatures below 1.5 °C as expected by the Paris Agreement, COP 21. The IPCC, International Panel on Climate Change, in the Special Report “Global Warming of 1.5 °C,” underlines how essential it is to stay below 1.5 °C compared to pre-industrial levels. To date, it is estimated that this overcoming could take place by 2040 (IPCC 2018).

Many actions are implemented to protect the forests, and the biodiversity they preserve,

through the protection of the territories but also an important reforestation work. The largest rainforest on Earth, that of Amazonia, is the forest in which the attention towards deforestation is greatest. Legal activity is often replaced by illegal activity which causes not only the loss of the forest but also endangers the lives of the indigenous peoples who live in those territories.

Forests and Land Degradation

The large and small forests present on Planet Earth are currently subject to deforestation by humans. In the early 1900s, the presence of 5 billion hectares covered by forests was estimated, and more than one billion was lost towards the end of the century (Brown 2008). It is possible to identify various more or less evident causes of the motivations that push humans to exploit forests. In tropical and sub-tropical forests (in Latin America, Africa, and Southeast Asia) deforestation means economic, political interests, such as agricultural expansion, expansion of pastures, mining, wood trade, and infrastructure. Five main factors can be identified that move man to forestry: demographic factor, economic factor, political-institutional factor, and socio-cultural factor (Geist and Lambin 2001).

The growth of the world population brings with it the increase in pressure that the human being exerts within the natural systems in which he lives. The demand for more food, more resources, and more space brings with it economic and political choices that affect ecosystems.

The expansion of agricultural activities, with the intensification and growth of industrial agriculture, with the expansion of the meat industry, with increasingly large and intensive farms, changes the traditional techniques of cultivation and breeding and needs more industrial commitments, greater infrastructures for the transport of goods, roads; therefore, it requires a change of use and different exploitation of the soil, more intense and unsustainable in the long run.

The growth of agro-industrial plantations is among the most important causes of deforestation

in tropical forests. The Amazonia area is the main witness. The activities that derive from it, legal and illegal, mean that the effects are not linked to a single activity when deriving from aggregate activities and therefore more impactful: we speak of “growth coalitions.” The growth coalitions are made up of different social actors who, in agreement with each other, pool the resources available to achieve their goal (deforestation, regional development, and agricultural colonization) (Rudel and Horowitz 1993).

Furthermore, large farms that require large spaces enter the logic of deforestation due to the need for grazing of large herds of cattle, goats, and sheep. These farms are estimated to have a very high impact, due to the large consumption of water, the production of methane gas, and the degrading impact on the soil (Brown 2008).

The paper industry also has a strong impact on large forests, just think that WWF denounces that 10% of the population exploits 50% of paper present on the entire planet. In addition, the demand for paper will grow as the population grows by 2050 (Bragonzi 2013). Although many developing countries have over time tried to limit timber exports for processing industries, at least formally, the World Bank reports say that market distortions, with pricing policies that see a very low cost of timber, have a significant impact on the increasing demand for wood.

Beyond the most obvious causes, however, many studies highlight a very complex variables (social, cultural, political-economic, and technological) that are not easily identifiable but which significantly affect deforestation. The data from the OECD, Organization for Economic Cooperation and Development, for example, reveal that 5–10% of the timber present on the international market is attributable to illegal and unsustainable activities. Furthermore, deforestation by border farmers gives them a property right on the land, increasing the possibility of advancing deforestation activities due to the need to increase income and family income. The poverty of the border areas also brings with it the phenomenon of “Land Grabbing,” with multinational protagonists, large companies and foreign governments,

private, who buy the land to the detriment of the poorest farmers and shepherds (a phenomenon not properly defined but known with negative meaning) (Vieri and Calabrò 2016).

Agriculture poor in resources, with insufficient food production for the local populations, leads to the problem of hunger and the inconstancy of proper nutrition. These situations, linked to a too low income, marginalization of local populations, and rampant unemployment, lead to unstable socio-political situations, resulting in internal wars and rebellions.

Although many developing countries have over time tried to limit exports of timber to the processing industries, at least formally, the data of the World Bank reports tell those market distortions, with pricing policies that see a very high cost of timber low, they have a significant impact on the increasing demand for wood.

International Actions and Actors

Many actions should be implemented to strongly reduce the exploitation of forest resources. Among them, it is important to consider better management of resources and greater accountability and transparency of stakeholders and policy. Educating people about the importance of forests and protected natural areas, educating the younger generations to respect nature is certainly essential for creating a culture that is more attentive to the environment. Planting new trees for reforestation in the face of the exploitation of forest resources is certainly one of the most effective actions. Many institutions, NGOs, associations, companies have protected and promoted actions and policies in favor of forests.

Forest Stewardship Council

The Forest Stewardship Council is an independent, non-profit international non-governmental organization (NGO), established in 1993 to encourage responsible management of forests and plantations. The association is committed to providing rigorous certifications that provide important information about the origin of the

products and compliance with the rules for sustainable forest management. Important are the Forest Management Certification (FM), which requires among other things the protection of ecosystem services, and the Chain of Custody (CoC) Certification for wood products, wood products, and wood-based products, but also mushrooms, honey, cork, and other products from proper forest management. In its “Global Strategy 2021–2026,” FSC focuses on a vision for 2050, which sees better market mechanisms, better forest policies and governance, and greater communication with people regarding the importance of forests.

Greenpeace International

Greenpeace International is an NGO that has always been committed, with direct and non-violent actions, to denouncing the activities that destroy nature and the Planet. Greenpeace, concerning forests, has always been committed to denouncing deforestation activities, especially in the Amazon rainforest.

NAFA: National Aboriginal Forestry Association

NAFA, National Aboriginal Forestry Association, is an association that deals with the involvement of Aborigines in holistic or multiple-use management of forests, through their reconstruction, and the business opportunities that derive from it. In doing so, NAFA promotes the sustainable use of forest resources, the maintenance, and care of Aboriginal traditions, and self-government.

WWF: World Wide Fund for Nature

The WWF, World Wide Fund for Nature, is an NGO that deals with the protection of nature. It has long been involved in combating the deforestation of the Amazon and has now activated a reforestation program in the Peruvian Amazon, in the Madre de Dios area, restoring 250 hectares of forest. It has also reconstituted 167 hectares of Atlantic forest, between Brazil and Paraguay, to reach at least 9,000 hectares. Also in Borneo, WWF is engaged in constant dialogue with the Indonesian government to ensure the sustainable management of the forests of Thirty Hills, a protected area of 40,000 hectares where the Sumatran tiger lives.

The Amazon Rainforest

The Amazon Rainforest covers an area of approximately 6.7 million km² and covers nine states: Bolivia, Brazil, Colombia, Ecuador, Guyana, Peru, Suriname, Venezuela, and French Guyana. Inside it flows the Amazon River, considered together with the Nile among the longest rivers in the world as well as being the river with the highest water flow. In the Amazon it is possible to trace about 10–15% of the known plant and animal species, however, among them, 265 species are at risk of extinction. The climate in the forest is equatorial. Deforestation is estimated to have caused a loss of 800,000 km² from the 1970s to today. The increase in temperatures associated with deforestation would cause an annual water decrease within the region (Alberti 2008) and at the current rate, the risk that the loss of further areas of the forest will lead to a 1.45 °C increase in temperatures by 2050 in Brazil compared to the annual average (Prevedello et al. 2019) is associated with a further probable decrease in rainfall. As pointed out by European research projects (Cordis), the great forest is at risk of a “circle of a progressive nuisance.”

According to the data made available by the WWF, there were about 30,000 fires in the month of August alone. The damage caused in Bolivia alone, in the Santa Cruz region, can be summarized as 3.5 million hectares destroyed (Ciarlariello 2019).

Many environmentalists try to denounce the bad health of the Amazon rainforest, associating themselves in the international discussion venues with the voices of the indigenous peoples living inside the forest and clamoring for respect for their home, showing the documented evidence of abuses that people live every day and the destruction waged.

International institutions, the UN, and many countries around the world are aware that protecting the Amazon means protecting the most important green lung on the planet. Tropical forests are among the hardest hit by deforestation. The countries of South America in the face of marked economic interests have not always responded with the same firmness. Illegal

associations, which derive important profits from the timber trade and from the cultivation of illegal substances, have responded with an escalation of murders of environmental activists who however have not appeased the complaints.

2030 Agenda for Sustainable Development

The 2030 Agenda, signed by 193 UN countries in September 2015, is an action program for achieving sustainable development by 2030. The Agenda is made up of 17 Sustainable Development Goals (SDGs) and 169 targets. In particular, SDGs 15, “Protect, restore and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss,” is centered on the need to protect forests and their ecosystems. Target 15.b also provides that developing countries are financed to ensure better management of forest resources and reforestation.

Keys-Issue

Deforestation, carried out without any care for ecosystems, cannot be sustainable in the long run. The loss of trees capable of removing climate-changing gases and releasing oxygen, changes in the water and carbon cycle, the loss of biodiversity, the change in land use and related activities, cannot be overlooked when it comes to the protection of forests and need adequate regulation and consequent control work. Forests are the lung of the Earth and as such must be treated and safeguarded from merely economic and political interests.

Future Directions

International policies that affect the limits to be imposed on deforestation will be necessary in the near future to prevent human activities from destroying one of the most precious assets of the

planet. Without forests, the increase in global temperatures will not find one of the main obstacles and there will be an increase in the incidence of climate change, with the growing fragility of the territories. Appropriate protection of the forests, especially the “virgin” ones, would allow not only indigenous peoples to continue living in the tradition as requested by them, but would also allow all native animal and plant species to live in their natural habitat. Important sectors such as timber, agro-industry and intensive farming, bioenergy, must necessarily be rethought with a view to sustainability and the protection of ecosystem services. The paper industry, which is also responsible for deforestation, will have to face the challenges of sustainable production, aimed at recycling, with the exploitation of ad hoc plantations that do not burden natural forests, with more equitable consumption. Many countries face deforestation with reforestation, planting new trees, and thus reconstituting forests destroyed by man’s greed. However, this activity does not apply to any type of territory: in unsuitable territories, the risk is that the water requirement of the tree drains the soil and disperses the little water present in the atmosphere, while in territories with mild and humid climates this activity of reforestation brings better benefits (Ferrara and Ferruggia 2007).

Many countries face deforestation with reforestation, planting new trees, and thus reconstituting forests destroyed by human, legal, and illegal activities. However, this activity does not apply to any type of territory, in unsuitable territories, the risk is that the water requirement of the tree drains the soil and disperses the little water present in the atmosphere, while in territories with mild and humid climates this activity of reforestation brings better benefits (Ferrara and Ferruggia 2007). The Royal Botanic Gardens of Kew identified 10 rules for reforestation in one of its publications: “1- protect existing forest first; 2-Work together (involving all stakeholders); 3-Aim to maximize biodiversity recovery to meet multiple goals; 4- Select appropriate areas for restoration; 5- Use natural regeneration wherever possible; 6- Select species to maximize biodiversity; 7- Use resilient plant material (with

appropriate genetic variability and provenance); 8- Plan ahead for infrastructure, capacity and seed supply; 9- Learn by doing (using an adaptive management approach); and 10- Make it pay (ensuring the economic sustainability of the project)” (Di Sacco et al. 2021).

The Covid-19 Pandemic has also revealed a correlation between the transmission of pathogens (especially zoonoses) and deforestation. Forests, which are in good health, protect humans from the risk of diseases originating from wildlife (ISPRA 2020).

The challenges to deforestation are many and important but the effort of all countries, of large multinational companies, will be necessary to achieve significant results in line with the need to achieve sustainable development.

Summary

Deforestation and forest degradation are activities dictated by economic and political interests. The agro-industry, the meat industry, and the pressures that derive from legal and illegal activities lead to the destruction of forest areas in the long term unsustainable. The loss of forest cover endangers biodiversity, the benefits of ecosystem services, and changes the water and carbon cycles. The change in land use, its exploitation, and the decrease in annual rainfall means that in the long run, it is losing its fertility with consequent drying up. In addition, the ongoing climate changes increasingly require the presence of plants for the removal of greenhouse gases in the atmosphere, which helps to contain global temperatures. However, large forests are increasingly endangered and a decisive intervention at global and especially local levels for their protection and care will become important in the near future, using the resources stored in them with a view to long-term sustainable development.

Degrowth

Rudi Kurz

Pforzheim Business School, Pforzheim
University, Pforzheim, Germany

Synonyms

Delinking; GDP (gross domestic product); Green growth; Growth paradigm; Growth policy; Innovation; Limits to growth; Planetary boundaries; Postgrowth; Sustainable growth; Transformation; UN SDGs (sustainable development goals, Agenda 2030)

Description

Degrowth of (rich) economies could have two types of causes. Either it can be the result of system-immanent forces or it could be the result of political design based on changing political priorities. Mainstream economics is analyzing the first type of causes and has identified a couple of factors that contribute to explaining the decline of growth rates and the (potential) phase-out of economic growth. The second type, degrowth by design, is driven by the incompatibility of ambitious environmental sustainable development goals (as formulated e.g., in the Paris Agreement on climate change) with economic growth – given that eco-efficiency increases turned out too small for delinking environmental resource consumption from standard economic growth. In both cases, challenging new questions need to be answered: How to manage transformation to low (no) growth without economic crisis? How to cope with declining industries (stranded assets and qualifications)? How to resolve distributional questions and conflicts without growth? How to

mobilize financial resources (taxes, capital markets) for investment in new infrastructure? As degrowth is still widely perceived as irrelevant, not much research results are available to cope with these questions.

Why Degrowth? The Relevance of the Degrowth Debate

The academic and political debate on degrowth is of high and increasing relevance especially for advanced rich nations for two reasons:

1. **New policy priorities:** The United Nations Sustainable Development Goals (SDGs, Agenda 2030, <https://www.un.org/sustainabledevelopment>) replace one-dimensional economic growth by a more comprehensive goal system (Meadows et al. 1972; Boulding 1966; Latouche 2010). If economic growth is incompatible with goals of higher priority (especially climate and biodiversity protection), it is no longer desirable. This aspect is analyzed part 2. Controlled and managed degrowth could then be an explicit policy goal of sustainability policy.
2. **Fading growth dynamics:** Responsible (economic, social) science has to be prepared for a phase-out of economic growth. What is the Plan B, if the dynamics of the economic system no longer produces increases of GDP year after year? And if Plan A, the stimulation of economic growth by government policy, is not working? The assumption of and the hope for ever-lasting economic growth is naïve and careless. Part 3 discusses causes of declining growth rates.

For both reasons, it is urgent to reinforce research on long-term implications of no-growth economies as well as the design of critical transformation processes. Part 4 outlines some aspects of degrowth policy.

Is Growth Compatible with Sustainable Development?

Economic growth, the increasing production of goods and services in an economy is related to increasing resource inputs and impacts on

eco-systems. If these impacts are larger than the limits formulated in environmental SDGs (e.g., on climate protection and biodiversity), growth is incompatible with these SDGs and hence with SD in total. Development is “sustainable development” only if it includes all dimensions, the socio-economic as well as the environmental. The analytical question is if it is possible to “delink” growth and environmental impact. The empirical question is if there is evidence that this is actually happening (see Jackson and Victor 2019; Kurz 2019).

Economic growth is measured as increase of real GDP. GDP represents the value of all end products in one year and “real” means that price effects (inflation) are eliminated. There is a huge literature on the critique of the GDP concept and on the mismeasuring which it induces. And many proposals have been made to correct and to add (see Stiglitz et al. 2009). In fact, the GDP concept has been developed as a tool of output measurement. It has never been intended as an indicator for wealth. If at all, GDP/capita might serve this function.

If production (GDP) increases then environmental impacts I will increase too – ceteris paribus (if nothing else changes). However, this relation is not fixed but there is a connecting variable: eco-efficiency I/GDP:

$$I = I/GDP * GDP$$

If I/GDP declines, I can decline – even if GDP grows. For example, 2% p.a. GDP growth rate would increase the GDP by roughly 50% in the period 2020–2040. If the environmental protection goal is to reduce impact I over that period by 50% then the formula reads:

$$1/2 = I/GDP * 1,5 = 1/3 * 3/2$$

Eco-efficiency has to increase by a **factor 3**, that is, the environmental impact of producing one unit of GDP in 2040 is reduced to one third compared to 2020. This implies an annual increase of resource efficiency of more than 5%. So far, there is no empirical evidence that such efficiency increase rates are possible over many

years. Most OECD countries show rates of 1–2% p.a. (see Kurz 2014). More details on “factor 4” and “factor 5” are provided in Weizsäcker et al. (1997) and in Weizsäcker et al. (2009).

Ambitious efficiency increases (like factor 3 in two decades) could delink (decouple) economic growth and environmental impact. But this would require an “efficiency revolution” which has not materialized so far. Government policy options to change this seem to be very limited. Moreover, if successful, stimulation of eco-innovation will stimulate growth and thus the intended reduction of impact I. This is called “rebound effect” (see ► “Rebound Effects of Eco-Efficiency”).

Based on optimism about future eco-efficiency increases and on the neglect of rebound effects, the concept of “Green Growth” (see Kurz 2014; OECD 2011) nourishes hope that the growth paradigm can survive. While critics point to the lack of empirical evidence, defenders of growth refer to the chance of increases in the future. At least related to essential natural resources (like ozone layer, climate stability, ecosystem services), the survival of mankind depends on “save operating space” (Rockström et al. 2009). With technological over-optimism, planetary boundaries could be violated and processes triggered which are out of human control (tipping points). Without evidence for upcoming quantum leaps in eco-efficiency, economic growth is the variable which has to be controlled. Under given conditions, the only form of green growth is degrowth (in rich countries).

In sum, given the empirical trend in efficiency increase, growth and sustainable development (e.g., climate protection) are incompatible. This holds not only related to climate protection goals (SDG 13) but also to material flows (material efficiency) and to biodiversity (efficiency of land use). As delinking by high rates of efficiency increase fails, ambitious environmental goals turn into restrictions for output (GDP growth). It is then necessary that a smaller scale of output contributes to reduce input (of environmental resources). In macroeconomic terms, this means a decline of GDP (degrowth); the micro-fundament is less consumption of private households (sufficiency, changes in lifestyle). Either (rich) nations give up their growth goals and

growth policy or they will fail to comply with their SDGs and hence shift incalculable burdens on (grand-)children. Either give up income or given up moral integrity. If the environmental sustainable development goals dominate, growth is no longer desirable.

The next analytical step is to put the efficiency factor in a more general context by applying the so called **IPAT** equation (see Kurz 2014):

$$I = I/GDP * GDP/person * persons$$

$$\text{Impact} = \text{Technology} * \text{Affluence} * \text{Population}$$

For the reduction of environmental impact I, three strategic options are available:

- **I/GDP:** reduction of the impact per unit of output (GDP), that is, **eco-efficiency**.
- **GDP/person:** reduction of income per person which is related to a reduction of consumption expenditure, a fundamental change in lifestyle, that is, **sufficiency revolution** in the rich countries (► “Sufficiency”).
- **Persons:** In most rich, countries population is declining (and aging). This could not be much accelerated over the next two to three decades and hence this option will be neglected here.

Applied to climate change the formula reads:

$$CO_2 = CO_2/kWh * kWh/GDP * GDP/person * persons$$

The goal of reducing CO₂-emissions could be compatible with economic growth, if carbon intensity of the energy system (CO₂/kWh) and/or energy efficiency of the economy (kWh/GDP) decline. One scenario for decarbonization within two decades could be: reduction of CO₂ per unit of GDP by 50% and switching to renewable sources for the “rest” 50%; a decline of population would allow for slight increases of GDP/person.

The interesting additional component and option in this equation is GDP/person, that is, per capita income. Less income – and hence less consumption (with constant saving rate) – could

reduce environmental impact. This seems to be a rather dismal perspective. So far the explicit promise and job of economics has been to increase per capita incomes as the most important determinant for well-being/happiness. The challenging question therefore is whether the end of growth (growing incomes) would be the end of the pursuit of happiness (► [“Sufficiency”](#)).

What could sufficiency and degrowth actually contribute to SD and what is the price in terms of income reduction? The difference between a (moderate) business-as-usual (+2% p.a.) and a degrowth scenario (−1% p.a.) is quite significant, 49 + 18, that is, 67 percentage points (Table 1). In terms of average annual income, the initial annual income of, for example, 36.000 € either increases to 53.640 € or it declines to 29.520 €, a difference of 24.120 €. To “digest” and to manage such a swing in perspectives and biographies is unprecedented in the last decades.

In sum: The degrowth issue really matters, both in the individual dimension (as individual life-changer) and in the macro-economic dimension (reduction of GDP). As sufficiency has a vital role for SD, government policy has to change. Instead of growth policy it has to be sufficiency policy, that is, policy which enables people to live a good life with less consumption of goods and services. And it is crucial that the rate of eco-efficiency increase does not decline, an empirical question that cannot be answered as there is no experience with longer periods of degrowth.

Growth Fading Away? Degrowth Ante Portas?

There is a wide-spread fear (even in) rich countries that drivers of economic growth might dwindle, that inherent dynamics of capitalism (competition and innovation) is lost, and that the

promise of ever increasing income and wealth no longer holds (e.g., Gordon 2016). Empirical data on the long-term growth trends reflect declining growth rates in almost all countries and that the benefits of growth are concentrated on a small group at the top. Many factors have been identified and discussed as determinants and (weakening, fading) drivers that might be crucial in the end phase of the growth era:

- Innovation/technological progress weakens
- Aging population (tends to be less innovative)
- Nationalism (anti-globalization)
- Productivity growth decline
- Re-distributional policies over-burden the rich entrepreneurial class (negative incentive effects)
- Increasing welfare state (consumption instead of investment)
- Work-life-balance (less willingness to work hard)
- Decay of infrastructure (complementary to private investment)
- Monopolization (stifling competition)

Additional barriers result from environmental sustainable development goals and from changing lifestyles (► [“Sufficiency”](#)) which could stop economic growth or turn it negative:

- Decarbonization will be the end of fossil energy consumption, dematerialization requires the reduction of material flows, the protection of biodiversity will restrict land use.
- Population will (has to) decline and sufficiency reduces labor market participation.
- Capital stock (industry, buildings, infrastructure) declines in transformation processes as stranded assets increase.
- Technological progress will focus more on eco-efficiency instead of labor productivity.
- The sufficiency trend reduces consumers’ demand (with negative effects on firms’ investment) and leads to “secular stagnation” (Summers 2016).

Randers (2012) uses the following simple “forecast model”:

Degrowth, Table 1 Economic growth projections 2020–2040

Year	Growth rate % p.a				
	3	2	1	0	−1
2020	100	100	100	100	100
2030	134	122	110	100	90
2040	181	149	122	100	82

GDP=GDP/worker × worker

With a declining (and aging) workforce (working hours), growth depends on (increasing) labor productivity. If this also stagnates (aging, service economy), growth phases out, the economy is converging towards the “stationary state” (Mill 1848; Keynes 1930).

In sum: The traditional expansive forces of innovation, ingenuity, and effort will continue to be strong drivers of economic growth. In addition, governments promise to rekindle growth by “whatever it takes.” However, it would be naïve and over-optimism to hope that growth will prevail forever. It is wiser to be prepared for an age without growth – and it is the job of economists to analyze the consequences and to deliver the new concepts for stabilizing the economy and society, especially resolving distributional conflicts in the absence of a growing cake. The minimal consensus now seems to be to make economies less growth-dependent. In case of (exogenously) declining growth rates, society has to be prepared mentally, institutionally and physically (infrastructure). This would increase stability of a society (resilience), thereby reducing the success chances for radical political parties. Social stability should not be put to the test, instead preparations for the no-growth-world should be intensified (pension systems, etc.).

Degrowth Policy

If degrowth is a necessary and unavoidable consequence of ambitious environmental sustainable development goals, this has consequences for economic policy. Growth policy, that is, growth stimulating measures are obsolete and have to be replaced by a degrowth policy. Such a policy has not yet been formulated and tested. There is some experience with reducing GDP growth rates in a short-term business cycle context, for example, by increasing taxes and reducing government spending. But a systematic policy to control and to slow down economic expansion seemed to be irrational so far. Although the diagnosis of “uneconomic growth” has been formulated already years ago (Daly 1996), no policy concepts are available. Is it possible to control and to manage macroeconomic growth rates? How to end an almost 100 year

phase of economic growth (soft landing)? Is growth “feasible,” can it be “designed” (Victor 2008; Jackson 2009) or is immanent “systems dynamics” dominating (Randers 2012)? Degrowth is not just a little technical change of a few percentage points, for example, instead of plus 2% p.a. in the past to minus 1% in the future.

For economics as a discipline, this is the end of the growth paradigm, which has dominated economics and all fields of policy on a global scale after WW II (Olson 1973; Schmelzer 2016). In fact, the challenge is to formulate a new paradigm for the postgrowth era (see ► “Postgrowth”). Economic theory could start by replacing “growth” by the more open concept of (economic) “development” – as outlined by Schumpeter (1911). Core idea is economic development as an open decentralized search process without growth orientation but emphasizing permanent, sometimes disruptive change and transition processes which could be cumulative and destructive or rather smooth (by design). To this core, the environmental limitations have to be added to create a new paradigm of sustainable development. Research on degrowth and on the postgrowth paradigm is of increasing importance. But it is difficult and time-consuming to replace an established paradigm (Kuhn 1962).

For the reorientation of economic policy after the growth era, two different building blocks are needed:

1. A long-term vision to replace the promise of the growth paradigm of a better future by producing more goods and services. The farewell to the wealth promise as we knew it “more, bigger, faster” is a cultural revolution. As incomes will decline, additional wealth and well-being has to come from different sources, pursuit of happiness redirected: labor conditions, leisure time, fairness, inclusion, participation, etc. This is no less than a cultural revolution (Illich 1973). For some ideas on the pursuit of happiness in the postgrowth society, see entries on ► “Postgrowth” and on ► “Sufficiency”.
2. A medium-term concept for the transition process over the next two decades, the “Great

Transformation” (Polanyi 1944; WBGU 2011). How to initiate and to design a phase of declining GDP? The challenge is to slow down in a controlled process without chain reactions (spill-over, overshooting), without triggering a downward spiral and economic crisis. This would endanger social stability and acceptance for any (environmental) sustainability goals.

Degrowth is not for ever but (only) for a transition period until a “sustainable” level is reached and economic development is (again) within “planetary” boundaries. This is a rough description which can be formulated more precisely, for example, for CO₂-emissions (carbon-neutral economy), for biodiversity (zero additional land “consumption”), for material flows (bio-based circular economy). Once the scale of economic activity is compatible with these limits, degrowth converge towards a stationary state with zero-growth of GDP. Under the surface of macro stability, on the meso- and micro-levels, innovation and change will continue. Other measurement tools will be necessary – beyond the System of National Accounts (SNA) and GDP to reflect that this is not the end of progressive human development (e.g., Human Development Index HDI, Gross National Happiness GNH).

A first step in degrowth policy would be to stop all forms of growth policy: Abolish all growth-stimulating measures, for example, in the tax code, revise deregulation, stop unspecific subsidies for R&D. Laws which define growth as goal for government policy have to be abated. Government expenditure has to be restructured, for example, infrastructure investment: no new roads, runways, and terminals – bike lanes and public transportation instead.

Then environmental limitations have to be “translated” systematically into “caps” (maximum tolerable quantities) – from CO₂-emissions to parking lots. The transformation process is characterized by the gradual implementation of such limitations on natural resource consumption, e.g. the disposal of CO₂ in the atmosphere (Stern 2006). As burning of fossil fuels has to end (decarbonization), decisions on the phase-out of

certain processes, products, and industries are necessary. The impact will not spread equally across the economy but will be concentrated in certain industries and regions. Examples are the phase-out of

- (a) Fossil-fuel power plants in Germany by 2038 (Kohleausstieg). This decision has been prepared by an inclusive commission and will be accompanied by structural adaptation measures of about €40 billion (for regions and 20.000 employees).
- (b) Fossil-fuel engine in vehicles: Some countries plan to end admission of new fossil-powered (internal combustion) engines by 2030 (e.g., Netherlands, Norway, Sweden). If these cars are allowed to be driven for ten more years, the mobility sector would be decarbonized by 2040. This has dramatic consequences for one of the dominating industries (automobile industry plus suppliers) in countries like Germany and in specific regions. Half of the jobs could be lost within two decades.

Such transformation processes need careful planning and preparation to make the descent calculable and to prepare for a soft landing. The process is conflict ridden and much depends on the resilience of institutions. People will lose their jobs and some will learn that their qualification is no longer relevant. Therefore, retraining has to be organized and if this is not suitable compensation payments have to be financed. Without transformation planning and transformation funds, resistance will be massive – and in many cases “successful,” that is, delay the transformation process.

A major challenge for degrowth policy is to avoid “overshooting” reaction of the system, that is, a self-feeding crisis (economic tipping point) with huge losses for all (like financial crisis 2008). Traditional crisis intervention mechanisms (monetary and fiscal) might be overburdened with this job. Switching a development path is different from correcting a cyclical economic downturn (recession).

Companies are used to a growth world and have no idea how to thrive in a no-growth

environment – where average entrepreneurial talent might not be enough. What could government do to better prepare companies and managers for the no-growth world? More competition or more co-operation? Higher profits to kindle entrepreneurial spirits? More venture capital for start-ups?

Intragenerational justice under degrowth conditions means more redistribution of incomes and wealth. As vulnerable groups (low-income households) have to be protected from decline of income, higher income groups will have to pay more taxes. How will the privileged react? Do the lucky ones in the lottery of life understand their responsibility and are they willing to share (more) with the less privileged? As conflict potential increases, investment in social capital (inclusion, participation, dialogue, and conflict resolution mechanisms) is vital and required today. The better prepared it is, the less painful will be the birth of a postgrowth society.

Deming 14 Points Model

Jie J. Zhang
Gustavson School of Business, University of
Victoria, Victoria, BC, Canada

What we need is cooperation and transformation to
a new style of management. – W. Edwards Deming

Synonyms

[Deming Management Method](#); [System of Pro-
found Knowledge \(SoPK\)](#)

Description

Deming 14 Points for management (Deming 1986) are 14 imperatives that Deming synthesized from his international consulting and teaching career spanning nearly four decades. According to Dr. W. Edwards Deming, these interrelated 14 Points work together to illustrate how the mechanistic style of management can be transformed to help everybody involved in the organization – employees, management, suppliers, and customers – to achieve long-term win. Deming 14 Points Model may also be used as “Deming Management Method” (Anderson et al. 1994), and they formed the core of the System of Profound Knowledge “SoPK” (Deming 1994).

Introduction

Deming 14 Points Model was grounded in Dr. Deming’s teaching of mathematics, statistics, and statistical quality control (SPC) methods (Shewhart 1931, 1939). His transformational management method was also informed by systems thinking and human psychology. In 1950, Dr. Deming was invited by the Union of Japanese Scientists and Engineers (JUSE) to teach the application of statistics to quality improvement in Japan. Dr. Deming’s teaching and consulting work in the 1950s played an instrumental role in helping Japanese producers revolutionize quality management and penetrate Western markets, which earned him global recognition as one of the top quality management gurus. Dr. Deming’s management philosophy and teaching were discovered by American manufacturing and service organizations in the 1980s when they faced stiff competition from Japanese products excelling in both quality and price. Established in 1951, the Deming Prize is an annual award given to both individuals for their contributions to the field of Total Quality Management (TQM) and businesses that have successfully implemented TQM (JUSE 2019).

Deming 14 Points Model and System of Profound Knowledge

Deming 14 Points are (Deming 1994):

1. Create constancy of purpose toward improvement.
2. Adopt the new philosophy.
3. Cease dependence on mass inspection.
4. End the practice of awarding business on the basis of price tag alone.
5. Improve constantly and forever.
6. Institute training on the job.
7. Institute leadership.
8. Drive out fear.
9. Break down barriers between departments.
10. Eliminate slogans, exhortations, and targets for the workforce.
11. Eliminate numerical quotas.
12. Remove barriers to pride in workmanship.
13. Encourage education and self-improvement.
14. Put everybody in the company to work to accomplish the transformation.

Deming elaborated these 14 Points as principles for transformation of Western Management in Chap. 2 of his book *Out of the Crisis* (Deming 1986, pp. 18–96). Deming's aim of proposing this new method of management is to halt the decline of American industry at the time and turn it upward. To this end, the Deming 14 Points Model provides insight into how things work, how they can be evaluated, and how they can be transformed. Some of the points focus on specific practice – for example, #4 End the practice of awarding business on the basis of price tag alone and #11 Eliminate numerical quotas. Other points focus on organizational structure design – for example, #9 Break down barriers between departments. It is important to note that no point stands alone. Effective implementation of the 14 Points *together* can lead to better thinking, extraordinary results, and win for everyone by stimulating different thinking, improving innovation, and enhancing life. Deming 14 Points were later integrated into the System of Profound Knowledge (SoPK) (Deming et al. 1992) which

Deming 14 Points Model, Fig. 1 Four interrelated areas of the Deming 14 Points Model (Deming 1994)

consists of four interrelated areas as illustrated in Fig. 1 (graph developed by the author).

Appreciation for a System

Deming defined system as “a network of interdependent components that work together to try to accomplish the aim of the system” (Deming 1994, p. 50). So the first thing to understand is the aim of the system. For businesses, the aim is to become competitive and to stay in business and to provide jobs by improving product and service. Deming compelled the management to awaken to this challenge and lead changes at the system level. To do so, the management must build understanding of the components of the production system, avoid the mistake of optimizing individual sub-components, and more importantly appreciate the interrelationships among the components. Cooperation is the key to achieving the aim of the organization. Therefore, “resolution of conflicts, and removal of barriers to cooperation, are responsibilities of management” (Deming 1994, p. 64).

Reducing Variation

All processes exhibit variation. Reducing variation can lead to improvement.

Used properly, statistical methods (Deming 1975) can help us understand variations in their context. There are two major types of variations. *Common cause variation* is random variation that is inherent to a stable system. Examples of

common cause inputs include people, equipment, knowledge/training environment, processes [and improvement], work policies, governance, and oversight performance management interactions/departments. *Special cause variation* is variation whose source is not inherent to a normal/stable system, but local or “fleeting events.”

According to resources published by the Deming Institute (<https://deming.org/>), common cause variation is distinguished from special cause variation by the following characteristics:

- Each factor contributes a small amount to the total variation.
- No one cause contributes significantly more than any other cause.
- All data are relevant for generating improvement.
- Asking “what happened?” is a low-yield and costly strategy.

Special cause variation is distinguished by the following characteristics:

- Special cause has a more pronounced effect than any single common cause.
- Can be identified and is generally not a normal part of the work.
- Management asking “what happened” is a useful strategy.

Theory of Knowledge

Deming maintained that knowledge is built on theory rather than experience alone. A theory is not without the risk of being wrong. However, knowledge can develop through systematic revision and extension of theory based on comparison of prediction with observation. This knowledge building process can be implemented through the Plan-Do-Study-Act (PDSA) cycle (Deming 1986) (illustrated in author-developed Fig. 2).

A PDSA cycle demonstrates how theory can be constructed from experience. It is also a cyclical approach to help ensure constant product and process quality improvement. This approach often relies on statistical process control (SPC) to monitor current process. Furthermore, workers

Deming 14 Points Model, Fig. 2 PDSA cycle applies a scientific method to test and carry out improvements (Deming 1986)

are trained and motivated to assess problems and improve process or product.

A core instrument in the theory of knowledge is operational definition. “An operational definition puts communicable meaning into a concept. Adjectives like good, reliable, uniform, round, tired, safe, unsafe, unemployed have no communicable meaning until they are expressed in operational terms of sampling, test, and criterion” (Deming 1986, p. 276). Operational definitions enable the transaction of business by allowing common understanding within the organization as well as with suppliers and customers. They ensure the clarity in communication to spread knowledge of how things are done and how changes can be made.

Psychology

Deming’s philosophy of management fully embraces the belief that people are born with a natural inclination to learn and experience joy in work. It is the job of the management to nurture the positive innate attributes of people. Management must give employees the right tools, knowledge (e.g., training and education), and systems to be able to succeed. Creating progress in meaningful work is central to fostering a work

environment where people take pride in their work. To this end, PDSA serves as a practical tool which empowers people to create meaning and progress in their work.

Management also needs to understand that people differ from one another and manage the system accordingly. It is important to recognize what motivates people. Intrinsic motivation is powerful because we are all working toward things that are much bigger than the task on hand. Deming advised the management to drive out fear because setbacks have a stronger influence on people than does progress.

Summary

Deming 14 Points are a set of clear instructions to the management on how to achieve long-term success for everyone. Drawing on his lifelong research and practice, Deming developed a theory of management that rendered the mechanistic style of management obsolete. The core principles where the 14 Points originate from – appreciation of a system, understanding variation, a theory of knowledge, and psychology – remain highly relevant as the human race transforms the current way of doing things and cooperates in addressing the “wicked problems” (Buchanan 1992) such as climate change, biodiversity loss, and inequalities.

Desertec

Irmgard Buder
Faculty of Communication and Environment,
Rhine-Waal University of Applied Science,
Kamp-Lintfort, Germany

Definition/Description

The Desertec concept was developed by the Trans-Mediterranean Renewable Energy Cooperation (TREC), a cooperation of scientists and the German section of the *Club of Rome* with the aim to tackle the key challenges of humankind – climate change, a secure energy supply for an increasing population, and water scarcity. Renewable energy mainly produced in the deserts

of North Africa together with renewable energy produced in Europe was supposed to secure the power supply in the EUMENA region (Europe, the Middle East, and North Africa) and to enable the operation of water desalination plants that could ensure the water supply in that area. Details of the concept were presented in a White Book (TREC 2007). In order to implement the concept, the Desertec Foundation was founded as a non-governmental organization in January 2009 followed by the Desertec Industrial Initiative (Dii GmbH) as a company with limited liability in October 2009.

The Concept of Desertec

“Clean Power from Deserts -Within 6 hours the world’s deserts receive more energy from the sun than humankind consumes within a year. This means that sufficient clean power can be generated from the world’s deserts to supply mankind with enough electricity on a sustainable basis. The DESERTEC Concept promotes the large-scale production of solar and wind power in the desert regions of the world, combined with a smart mix of photovoltaics, hydropower, biomass and geothermal energy” (Desertec Foundation n.d.).

The Desertec concept addressed the global challenges of climate change, limited availability of fossil fuels, and water scarcity (TREC 2007). It was intended to create a network that was able to provide electric power produced by renewable energy (see ► “Renewable Energy”) in the EUMENA region, which includes North Africa, the Middle East, and the European Union countries (Tagliapietra 2017).

Climate change was seen as the key challenge of human kind (see also ► “Climate Change”), since “Energy from sun, water from the skies and food produced by plants” are the most important parameters of human life which are determined by the key climate parameters “solar radiation flux density, clouds and precipitation and surface properties (mainly vegetation)” (TREC 2007). In the IPCC report of 2007, a change of climate due to human activities had been observed since 1759, and an increase of the

global temperature by $0.74^{\circ}\text{C} \pm 0.18^{\circ}\text{C}$ between 1906 and 2005 had been measured (IPCC 2007). Without a reduction of greenhouse gas emissions (see ► “Greenhouse Gases”), a further increase of temperature, which was supposed to be much faster than the temperature changes in previous periods, had to be expected.

Therefore, a reduction in the emission of greenhouse gases, especially carbon dioxide emissions by combustion of fossil fuels (see ► “Carbon Emissions”), was seen as mandatory. The limited availability of fossil fuels was also regarded as an issue: the global energy demand had been constantly increasing since 2007 (BP 2019) although the availability of fossil fuels and nuclear fuels like uranium and thorium is limited (BGR 2017) (see ► “Peak Oil”).

Another key issue addressed was the water scarcity especially in the MENA region (GEO 2000). Water scarcity and freshwater pollution were expected to be major emerging issues (see ► “Water”). In 2025 water scarcity of less than $1000\text{ m}^3/\text{person}/\text{year}$ was expected among other countries for Morocco, Algeria, Tunisia, Libya, and Egypt as well as the countries addressed in the MENA region (GEO 2000). Therefore desalination plants for seawater were proposed. The estimated energy consumption was around 4 kWh of electric power per cubic meter freshwater (TREC 2007).

Countries of the Middle East and North African region (MENA) region were supposed to cooperate with the European Union (EU27) in order to provide electric power for a renewable energy supply (see ► “Energy-renewable”).

Concentrated solar power plants (CSP) were regarded as the key element in power supply (DLR 2006) (see ► “Sustainability and Solar Energy”). It was suggested to concentrate direct solar radiation via collectors, generating high temperatures, and provide heat for efficient steam production. The generated steam could be used in the same way as the steam in conventional steam power plants which are powered by fossil or nuclear fuels. Since the storage of heat is technically feasible, this type of power plant could produce power on demand and during nighttime (Quaschnig 2016; TREC 2007). If longer

periods with not sufficient sunshine were expected, concentrated solar power plants could be combined with other heat sources such as fossil fuels or biofuels and be operated as hybrid plant (DLR 2006). One example of a hybrid installation of concentrated solar power with natural gas is the Ivanpah power plant in California which started operation in 2014 (NREL [n.d.](#)).

Concentrated solar power plants also “can provide steam for absorption chillers, industrial process heat or thermal seawater desalination” (DLR 2006). The feasibility of such concentrated solar power plants was also shown in another study (Trieb et al. 2009).

Other renewable energy sources proposed for the project were wind in the coastal regions of the EUMENA region with an estimated capacity of 2000 TWh/y, geothermal energy with an estimated power output of 4000 TWh/y, hydropower, and power from biomass using municipal and agricultural organic waste and wood (DLR 2006).

Due to geographic conditions, power plants using solar power were mainly proposed for the MENA region and southern Europe (mostly south of Spain and Italy); hydropower was proposed for hilly regions in Morocco, Spain, Scandinavia, and the Alps; wind for the coastal areas in Morocco, Spain, United Kingdom, France, and Poland, and geothermal energy for Italy and Iceland (TREC 2003).

To distribute the electric power derived from renewable energy, high-voltage direct current lines were proposed, since this system has lower transmission losses than high-voltage alternating current lines and enables the control of distribution and the direction of the current. The power supply to Europe should be derived by sea cables between Morocco and Spain, Tunisia, and Italy and a land power line through the Middle East. The installation of a “super-grid” was seen as a challenge, but its feasibility was asserted by DLR (DLR 2006).

Desertec Foundation

Desertec was first developed as a concept by the Trans-Mediterranean Renewable Energy

Cooperation (TREC) (Tagliapietra 2017). TREC was founded in 2003 by an initiative of the *German association of the Club of Rome*, the Hamburg Climate Protection Foundation, and the National Energy Research Center of Jordan (NERC) (e5 – European Business Council for Sustainable Energy e.V. [n.d.](#)). It formed a network of scientists, experts, and politicians, who were active in the field of renewable energy. The aim was the development of sustainable and renewable energy supply for Europe making optimal use of the locational advantage of the deserts in North Africa especially for solar thermal energy (Holznagel and Schumacher 2009).

The Desertec Foundation was founded as a nonprofit foundation on January 20, 2009, by scientists, politicians, and economists supported by Prince El Hassan bin Talal from Jordan and the *German Association of the Club of Rome* (Desertec Foundation [n.d.](#)). Target was the implementation of the Desertec concept for electric power supply basing on renewable energy in North Africa, Middle East, and Europe. The benefits of the project and the high energy potential of the desert regions should be communicated, and a framework for global transition to renewable energy should be established. Further knowledge transfer and scientific cooperation should be supported, and cooperation with the private sector should be promoted (Desertec Foundation [n.d.](#)).

Desertec Industrial Initiative Dii GmbH

In order to promote the cooperation with industry, the Desertec Industrial Initiative (Dii GmbH) with a headquarters in Munich was founded as company with limited liability in October 2009. Its aim was to support the implementation of the Desertec concept in the EUMENA region. Among others the founding members were ABB, Deutsche Bank, RWE, and First Solar. In 2012 Dii GmbH consisted of 21 shareholders, including technical conglomerate companies, energy companies, and banks. Another 36 companies were associated partners (Dii GmbH 2012). The objectives of Dii GmbH were described as follows:

- *Create a favourable regulatory environment*
- *Enable concrete reference projects*
- *Develop a Rollout Plan by 2050*

(Source Dii GmbH 2012)

Dii GmbH did not directly invest in renewable power projects but acted as a facilitator of power projects. It supported several renewable energy projects in the MENA region, but the focus was mainly on the electric power supply of the region (Calderbank 2013).

A drawback was the refusal of Spain to sign up an agreement to construct power interconnector to Morocco (Deign 2013). Increasing shares of renewable energy in the European markets started to be an issue (Calderbank 2013).

In 2013 the Desertec Foundation withdrew from the contract with Dii GmbH due to differences in the consortium concerning the question, whether the focus should be on power supply in Europe or the in the MENA region (Deign 2013; Mathiesen 2013). In 2014, 14 of 17 companies withdraw from the consortium. By the end of 2014, Dii GmbH was closed. Only three of its partners – RWE (Germany), ACWA Power (Saudi Arabia), and State Grid (China) – continued their cooperation in form of a consultant firm with its head office in Dubai (Balser 2014).

Outcome

Due to the end of the cooperation between the Desertec Foundation and the Dii GmbH and the withdrawal of many important stakeholders from Dii, the Desertec project was seen as a failure (Balser 2014).

The sustainability of the project was already disputed in 2011 (Klawitter and Schinke 2011) due to the focus on centrally regulated large-scale imports of renewable energy from the MENA region, a region with increasing demand for electricity (Zhang et al. 2017). Another issue was the energy security in the European states, if they relied on electricity imports from North Africa and the Middle East.

Interest in the project faded with increasing renewable energy production in Europe

(Calderbank 2013) and the Arabian Spring, which started in 2011. In 2014 the Desertec concept was abandoned. Nevertheless Desertec contributed to the setup of big CSP installations in Northern Africa. In 2016, for example, the first phase of the biggest CSP plant worldwide with an expected capacity of 500 MW was launched in Ouarzazate, Morocco (World Bank 2016). Parabolic troughs were used for Noor Ouarzazate I and Noor Ouarzazate II. In the third installation, Noor Ouarzazate III, heliostats have been used to concentrate the solar light on a tower. Noor Ouarzazate III has a gross production capacity of 150 MW and a storage capacity for thermal heat of 7.5 h of production (SolarPaces 2018).

In sum non-hydropower renewable power generation in the MENA region has increased tenfold and reached a production of almost 23 TWh (Zhang et al. 2017).

Summary

Desertec was a vision to create a network that provides electric power produced by renewable energy through the EU/MENA region, which is North Africa, the Middle East, and European Union countries (Tagliapietra 2017). The target was to solve the big challenges of human kind: climate protection, energy security, and freshwater supply.

The basic idea was that the world's deserts receive more energy from the sun within 6 h than humans consume in a year. Even if only a small part of this energy could be transformed into useful energy, e. g., electric power, the amount of energy which can be harvested in deserts was expected to be high enough to cover a significant share of the power demand of the whole EU/MENA region.

Further the water scarcity of the MENA region was addressed, and the idea was developed to build desalination plants which should be powered by renewable energy, especially concentrated solar thermal power plants in order to produce freshwater. This type of renewable power plant was suggested since there is a high solar radiation in the deserts of North Africa during

daytime, and power production during nighttime is also feasible when storing the heat (Quaschnig 2016). The generated power should be distributed to the EUMENA region via high-voltage direct current lines. It was proofed to be possible to cover high shares of the increasing power demand in the EUMENA region through renewable energy by 2050 (DLR 2006). For the implementation of this vision, the Desertec Foundation and Desertec Industrial Initiative (Dii GmbH) – a company with limited liability – were founded in 2009 with the target to develop guidelines to invest and finance the transnational power supply by 2050, providing studies of feasibility and showing feasibility in reference projects. Due to the lack of progress and conflicts about the main aim, the Desertec Foundation and the Dii GmbH stopped their cooperation in 2013 (Deign 2013; Mathiesen 2013). In 2014 the consortium of Dii GmbH was dissolved and transferred into a consulting firm (Balser 2014).

Desertification

Antonio Castrofino

Unitelma Sapienza University, Rome, Italy

Synonyms

[Land degradation](#); [Soil consumption](#)

Definition

Desertification is defined as the process of loss of chemical, physical, and biological capacities of the soil that degrade it to the point of making it arid and desert, with the disappearance of ecosystem services. Soil is a nonrenewable resource as approximately 2000 years are considered necessary for the regeneration of degraded soil, to the point of becoming inhospitable to life (Scholes and Noble 2001). Desertification is the “reduction

or destruction of the biological potential of the land that can lead to desert conditions” (UNEP 1977). This process is natural, both due to the erosive action of water and wind and due to human activity that through unsustainable practices, including agricultural ones, excessive grazing, deforestation, and land-use change, degrade the land by exploiting its natural properties to the point of impossibility of reuse. The ongoing climate changes, with the growth of temperatures and the decrease in rainfall, accelerate and increase the risk that more and more territories on the planet will soon see their neighboring deserts advance and more and more territories begin a slow but constant process of soil degradation.

Introduction

Especially in the last century, the desertification process has been affected by its rapid acceleration. After the Nairobi Convention in 1977 in Paris, the United Nations Convention to Combat Desertification (UNCCD) of 1994 was born out of concern about the evident ineffectiveness of the first actions put in place (Bologna 1998). The Paris Convention defined desertification as “land degradation in arid, semi-arid and dry sub-humid areas, attributable to various causes, including climatic variations and human activities” (UNCCD art.1.a) and introduced climate change as also the cause for the first time.

Land degradation is “the reduction or loss of ability to produce or maintain renewable natural resources due to external factors acting on the soil” (Ferrara and Ferruggia 2007). Decreased rainfall, drought, and increased temperatures but also microorganisms that, thanks to these factors, make their appearance in certain territories can lead to a greater risk of natural erosion. Large plantations and intensive agriculture, irrigation, large animal farms, urbanization, economic activities, related deforestation, exploitation, waterproofing, and destruction of the soil are among the causes of degradation and risk of erosion due to human beings.

For this reason, the UNCCD aims at sustainable development and hopes that national action plans (NAPs) will be implemented both to reduce soil degradation caused by climate change and to control related anthropogenic activities.

Desertification, the UNCCD Law Enforcement Actions

Desertification, one of the possible effects of land degradation, brings with it an environmental problem but also a social and economic one, especially in arid and semiarid territories (especially in the territories of the African continent). So all the participants in the 1992 Rio de Janeiro Summit, an important moment for the adoption of the Convention on Biological Diversity and the United Nations Framework Convention on Climate Change, decided that the time had come to tackle the issue of advancement of deserts and soil degradation.

In 1994 in Paris, some criteria were decided that each territory should follow: it was necessary that the local populations could freely decide to act in contrast to land degradation if they had the tools and that they would treasure the mistakes of the past. A step forward was also needed, in some territories and on land and property law. It was necessary to integrate these planned actions within the national program of each country so that it could move toward sustainable development and that there was cooperation between countries that had encountered the same problem. The Paris Convention was signed by 170 countries and is considered one of the three Rio Conventions along with the two mentioned above.

In recent decades, unfortunately, the actions to combat climate change and desertification have not been sufficient to tackle the problem decisively. However, many actions have been taken to limit the advance of the deserts. Among these, the most important is the decision to create in 2007 the “Great Green Wall” in Africa to contain the great Sahara desert. This green wall, which is expected to cover 8000 km, is intended not only to combat climate change in the area but also to

improve the difficult living conditions of the populations living around the great desert and in the Sahel area.

The UNCCD in 2007 adopted a Strategic Plan 2008–2018 to create a strong collaboration at the institutional level for the fight against desertification and its effects, especially in countries most in difficulty in the face of advancing drought. The UN then adopted, in 2015, the 2030 Agenda to achieve sustainable development 2030. This Agenda, made up of 17 Sustainable Development Goals (SDGs) and 169 targets, provides for objective 15 “Protect, restore and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss.” The related third target of SDG 15 (15.3) places the fight against desertification at the center.

Subsequently, in 2017, the UNCCD, to follow up on this target, adopts the “2018–2030 Strategic Framework” (UNCCD 2017a) to achieve the “Land Degradation Neutrality” by 2030 defined as “A state whereby the amount and quality of land resources, necessary to support ecosystem functions and services and enhance food security, remains stable or increases within specified temporal and spatial scales and ecosystems” (UNCCD 2017b). In COP12 in Ankara, a “Scientific Conceptual Framework for Land Degradation Neutrality” was proposed to guide for achieving this goal. This proposal was approved in the subsequent COP13.

The Factors of Land Degradation

Within the Communication “Towards a Thematic Strategy for Soil Protection,” COM (2002) 179, the European Commission has identified eight factors that affect land degradation and lead, as an extreme consequence, to desertification:

- Erosion
- Decrease of organic matter
- Soil contamination: local or widespread

- Soil waterproofing
- Soil compaction
- Decrease in soil biodiversity
- Salinization
- Floods and landslides

The Great Deserts

There are three different types of deserts on Earth: hot, cold, or polar deserts.

Hot Deserts

Hot deserts are characterized by constantly high temperatures. The affected areas are subject to desertification due to human activities and climate change.

Sahara Desert

The Sahara desert covers an area of over 8,000,000 km², thus occupying an area equal to 27% of the entire African continent. This important desert falls within the borders of several states: Algeria, Chad, Egypt, Libya, Mali, Niger, Mauritania, Morocco, Sudan, and Tunisia. In the Sahara desert, 50–100 mm of rain/year falls, depending on the area, and summer and winter temperatures are between 45 °C and 50 °C in summer and 11 °C and 26 °C in winter. The high temperatures, however, also touched the area above 55 °C (Goudie 2002). The temperature fluctuations are very strong between day and night. The Sahara, like all deserts, expands during the winter season and then contracts during the summer season. Due to its considerable extension, it has several “eco-regions” within it which have different climatic, flora, and fauna characteristics, so that, in addition to the areas where the flora is completely absent, there are areas of savannah and Mediterranean steppe. The sandstorms of the Sahara desert are also known for their ability to cross the Mediterranean Sea, carried by the wind to northern Europe. Being the Sahara desert, a “hot” desert, due to human activities and ongoing climate change, it is expanding. According to some studies of the University of Maryland, carried out on its size, it has been found that the desert

has increased by 10% since 1920 (Thomas and Nigam 2018). The semiarid belt of the Sahel, to date, is more subject to erosion and seriously threatens the populations that inhabit the neighboring territories and their economies based mainly on agriculture. Lake Chad, which has lost around 90% of its basin in the past 50 years, is witness to this serious situation.

Kalahari

The Kalahari desert covers an area of approximately 930,000 km² (Logan and Silberbauer 2019) and is characterized by its red sand. Its extension sees it as part of the territories of Angola, Botswana, Namibia, and South Africa. Summer temperatures record variations from 21 °C to 46 °C, while in winter temperatures drop to −12 °C at night. The flora changes according to the desert area. To the south, the desert has a flora consisting of a few trees and dense scattered shrubs; in the center instead, it presents several species of acacia as well as shrubs and herbs. In the north, on the other hand, there is luxuriant vegetation, deciduous forests, and palm trees. The famous baobab tree lives in this desert. The flora that populates the Kalahari desert is composed in the south by various species of antelopes, wildebeests, and gazelles, while in the north (as for the flora) the fauna is much richer. There are elephants, giraffes, buffaloes, zebras, antelopes, and warthogs but also lions, leopards, and hyenas as well as other small rodents. From the studies carried out on groundwater, it has been possible to reconstruct the temperatures from the Pleistocene to today, and it has been found that the current temperatures are about 5.2 °C/1.5 °C higher than in the past (Kulongoski et al. 2004).

Rub 'al-Khali

The Rub 'al-Khali desert, the “empty quarter,” as the tradition of the populations of the Arabian Peninsula defines it (after the first three “empty” that tradition wants to be heaven, Earth, and sea), covering an area of 650,000 km², is the largest sand desert in the world and is home to important oil reserves. In fact, in its territory, there is the well of Ghawar, the largest in the world.

Its considerable extension places it within the national borders of Saudi Arabia, Jordan, Iraq, Kuwait, Qatar, the United Arab Emirates, Oman, and Yemen. The “star dunes” that form in this desert reach in some cases 250 m in height and are one of its most attractive peculiarities. The summer and winter temperatures that occur in this desert are between 47 °C and 51 °C in July and August and the minimum 12 °C in January and February. Precipitation does not usually exceed 35 mm/year. The fauna consists mainly of arachnids and rodents. The flora, where present, mainly consists of very sparse shrubs. The ongoing climate changes show a constant trend of the increase in temperatures (0.51 °C/decade in the wet season and 0.72 °C/decade in the dry season) and a reduction in rainfall in the interior and an increase in the coastal one (Almazroui et al. 2012).

Great Victoria Desert

The Great Victoria Desert covers an area of Australia of approximately 240,000 km². Temperatures are always hot with inverse lows that drop to no more than 18 °C. The rains recorded are not intermittent but between 150 and 230 mm/year (Pell et al. 1999). The flora covers less than 10% of the area and is mostly composed of acacias and desert vegetation; the fauna instead sees several species of reptiles and rodents, as well as mammals, such as the dunnart of the dunes, and different species of birds, including the Australian pheasant. The Great Victoria Desert, together with the other Australian deserts, is currently the subject of great attention due to the ongoing climate change. In 1995, it was estimated that over 42% of Australia's 5 km² was at risk of desertification due to the drought which has also proven to be a real danger to agriculture and ecosystems in recent years. The upsetting fires of 2020 that destroyed about 200,000 hectares of forests, protected areas, and natural parks in Australia highlight the fragility of this country in the face of the problem.

Cold Deserts

Cold deserts are characterized by high temperatures in summer and very cold in winter. These

deserts are subject to desertification due to human activities and climate change.

Gobi Desert

The Gobi desert covers an area of 1,530,000 km² (Heshmati and Squires 2013) and is part of the territories of Mongolia and China. The desert consists mainly of rock rather than sand, and its composition is chalk and halite. The recorded annual temperatures highlight large hikes between summer and winter with temperatures reaching −40 °C in winter and 45 °C in summer. The flora is mainly composed of grasses and small scattered shrubs. The fauna is composed of different species of animals: camels, Mongolian gazelles, and black-tailed gazelles. The presence of the Mongolian wolf is one of the most fearful predators for herbivores. In the Gobi desert, there are numerous rodents and different species of birds including the desert falcon and the highland buzzard. The data collected by the “Envisat” satellite, presented in Milan during the “Living Planet Symposium 2019,” have shown that human activity, from deforestation to sheep farming, is among the causes that are most causing the expansion of this desert causing great concern for local agricultural activities.

Patagonian Desert or Patagonian Desert

The Patagonian desert, or Patagonian desert, covers an area of about 673,000 km² and falls within the territories of Argentina and Chile. The Andes mountain range is the main cause of the dryness of this territory since it creates the so-called rain shadow. Rainfall in the Patagonian desert is less than 200 mm/year in 37% of the region. The average annual temperature varies from the north (15 °C) to the south of the region (3 °C) (Gaitán et al. 2019). The flora consists of shrubs typical of cold deserts, while the fauna sees among its most famous animals the lama, the armadillo, the Patagonian weasel, the puma, and the desert iguana. Studies carried out in this region reveal that the increase in temperatures due to ongoing climate changes, with the relative greater or lesser amount of rain falling annually, will cause an important change within ecosystems,

with a different growth of flora, more shrubs, and fewer types of grass, and a reduction in the biodiversity of the species. The change in the driest area will lead to an increasing dysfunction of the soil nutrient cycle with a significant increase in the risk of erosion. In 2000, the MARS (Spanish acronym for Environmental Monitoring Arid and Semiarid Regions) monitoring system was born, a network that has the task of providing and exchanging useful information between different research teams about the evolution of desertification of the Patagonian territory.

Polar Deserts

The polar deserts are characterized by perennial ice and snow, therefore by very cold temperatures. These deserts are not subject to desertification but are subject to temperature variations caused by human activities and climate change.

Antarctica

Antarctica covers an area surrounding the South Pole of approximately 13,100,000 km². Winter and summer temperatures range from -26°C in December and January to -55°C in July and August. Precipitation: less than 55 mm of water/year falls within the continent, while between 300 and 600 mm/year also falls on the coast depending on the temperatures; if more rigid, we will have less rainfall (the air contains less humidity). The fauna that populates Antarctica is made up of several species of penguins, and the sea is home to several large species of cetaceans. The bird species that populate Antarctica are mostly made up of albatrosses, procellarias, and seagulls. The flora consists mainly of mosses and lichens as well as several species of mushrooms in the coastal area. Animals and plants must be suitable to withstand the extreme temperatures present on this continent. For the preservation of the flora and fauna of Antarctica on December 1, 1959, the Antarctic Treaty was signed, also known as the Washington Treaty which “froze” any possible territorial claim by any of the 12 states that were signatories at the time. In 2019, 54 countries are adhering to the treaty. The ongoing climate changes also put the Arctic desert of Antarctica

in serious danger since the melting of its cap, due to the increase in global temperatures, could cause a sea level rise of about 66 m. It is estimated that 6400 tons of ice was lost in the period between 1992 and 2018, making it 40% responsible for the global rise in the seas (7.2 mm) (Shepherd et al. 2020).

Arctic

The Arctic covers a surface that extends from latitude $66^{\circ} 33' 44''$ north to the North Pole. Unlike Antarctica, it is not a continent but an ocean that also extends to the mainland, thus occupying the territories of many neighboring countries: the United States, Canada, Greenland, Iceland, and Russia. Winter temperatures reach up to -58°C in the winter and in summer it changes from -10°C to 10°C . The fauna of the Arctic is composed of mammals including the polar bear, wolves, foxes, and arctic hares. Species such as seals, walruses, and different types of cetaceans live in the seas. The flora is mainly composed of mosses and lichens but also 400 species of angiosperms and small shrubs. On the Arctic, as there is no treaty similar to that of Washington for Antarctica, the rules of international law are in force, in particular, those of the United Nations Convention on the Law of the Sea signed in 1982. Climate change, from the studies carried out, in the last 40 years has led to a sharp reduction in the extent of this Arctic desert.

Desertification: Human Activities

Deforestation carried out by humans, associated with the wood industry (for burning and construction), the paper industry, intensive agriculture, and the expansion of large farms, is among the most important causes of the creation of the so-called new deserts. The cutting of large forests brings with it a loss of humidity and soil protection; the subsequent intensive exploitation concludes the process of degradation of the organic substance (intended as living material or that has been) which makes it fertile. In this sense, both the “buffer capacity” of the soil, that is, the

ability to neutralize the acidifying substances (pH), and the “carbon cycle” must always be kept in mind.

The soil exploited with mechanization, new technologies (including innovative), and the increasingly search for a “simplification of agroecosystems” always leads to the greater fragility of the territories and the loss of their resilience capacity. The fragility of the soil, deforestation, and the decision to create pastures and livestock or intensive monocultures also creates a loss of both animal and vegetable biodiversities.

The issues of large animal farms for the meat industry, genetically modified organisms between crops, intensive monocultures, patents on seeds, and crops for energy purposes are much discussed today. The latter in particular is the subject of debate as they could, on the one hand, reduce the use of fossil fuels and therefore reduce CO₂ emissions, but, on the other hand, they would certainly produce competition on land use (and consequently economic and social instability) as well as have no guarantee of continuity of supplies (APAT 2008).

The human being with his activities is therefore the cause of the creation of deserts as well as their expansion. The need to advance and have more and more space derives from various needs: from greater production of food to feed a constantly growing world population up to the need to expand large production and urban centers.

The soil dedicated to agriculture is worked and exploited until its progressive loss of fertility. The use of chemical fertilizers and pesticides is also accelerator of its definitive sterility. Excessive irrigation systems also constitute soil salinization factors which are among the main causes of desertification.

Emblematic fishing boats are stranded in the sand of Lake Aral, between Uzbekistan and Kazakhstan, which has now become desert from a basin containing salty waters. From 1960 to 2016, the lake lost 75% of its waters due to human exploitation that diverted the two rivers that flowed into the basin for intensive cotton crops.

Desertification: Ongoing Climate Change

The natural causes that created the oldest deserts on the planet are “the air masses of dynamic anticyclones (i.e., anticyclones like that of the Azores) located in the subtropical belt, which oscillate moving north during the boreal summer (and winter austral), and southward in the northern winter (and the southern summer). The major world deserts are located right in correspondence with these permanent anticyclones” (Ferrara and Ferruggia 2007). This atmospheric circulation falls within the so-called Hadley cell. The natural deserts all have ancient origins. Just think that the Sahara started to expand its borders around 8000 years ago.

The ongoing climate changes, with increasing temperatures, the consequent change in the hydrological cycle (including extreme events of drought and floods with landslide and landslips), put the soil and its elements under greater stress. Intensive human exploitation of the soil causes these meteorological events to further and often permanently damage the soil, making it increasingly arid and no longer allowing it to be recovered.

Climate change, according to WMO forecasts, will cause a decrease in the yield of agriculture, bringing entire populations to their knees, especially in Africa and tropical regions. The salinization of agricultural land will instead affect farmers in South America. These changes will lead millions of people to migrate from their territories of origin in which it will become possible to live, thus feeding the phenomenon of climate migration.

Key Issue

The phenomenon of desertification is a phenomenon that leads more and more populations to wars and clashes (such as those in Darfur and Sahel) for the control of resources or forced migration due to the decrease in arable land in their territories. This is most noticeable in the poorest countries (Brown 2008).

Human activity is among the main causes of the advancement of existing deserts and the creation of “new deserts.” Intensive agriculture, pastoralism, intensive farming, and deforestation are among the main causes of desertification caused by the human hand.

The ongoing climate changes cause an increase in the aridity of the soil in hot and cold deserts. In polar deserts, it is not possible to speak of desertification as described in the definition, but the increase in global temperatures is leading to their transformation highlighted by a progressive reduction of ice.

Future Directions

Agriculture and pastoralism, together with other human activities, have always produced profound transformations of the territories. Climate changes related to these activities and related to natural climate cycles (anticyclones), with the action of water and wind, have then led to a strong acceleration of soil degradation. This degradation not only affects the already existing deserts but endangers many areas at risk of desert transformation.

Arid, semiarid, and dry subhumid areas are at risk of desertification all over the world. The fight against climate change, and therefore the human activities that cause it, must necessarily deal with the consumption and degradation of the soil. Only with programs aimed at sustainable use of the soil, attentive to the conservation of its chemical and biological characteristics, to reforestation, and to the contrast of soil consumption and waterproofing, can they stop the phenomenon of the advancement of deserts and can they put a stop to wars dictated by the resources and climatic migrations that affect and could still affect tens of millions of people.

Summary

Land desertification is the extreme and final consequence of factors such as erosion, decrease in organic matter, soil contamination (local or wide-spread), soil sealing, soil compaction, decrease in

soil biodiversity, salinization, floods, and landslides. It is possible to define the soil resource is a nonrenewable resource in the life of an individual and its maximum degradation to the desert is the cause of severe food, economic, and social problems, which lead to wars for the management of resources and migration. The great deserts are advancing not only for the unsustainable exploitation of the Earth but also for the ongoing climate changes that aggravate the drought of the arid and semiarid territories, complicating the living conditions of the populations.

Definition

The central theme is the development of weak areas; a development aimed at reducing the differences between countries to achieve new and more shared global geopolitical balances. Kofi Annan, not long ago, defined sustainable development as an abstract idea to be made real in this century. Today, building on the mistakes made, the step must be longer, as the development to which we must strive is sustainable, but also balanced and independent (Sciarelli and Rinaldi

2018). Foreign material and immaterial resources must be used for the creation of autonomous development, not a welfare state dependent on foreign aid. Capital and international skills are a key to launching development but they must have a beginning and an end.

In our opinion, economic and social growth must be based on the culture of a country, which means respecting local traditions, religions, languages, and leading all this toward a contemporary vision of the country itself and a connection with the surrounding world. The growth strategy must be the key to development for a country.

The definition of general and specific objectives, resulting from a careful strategic analysis, must be the basis on which to build any development path. The consideration of the actors involved and to be involved and the knowledge of the essential skills in the short and long term become necessary factors for planning a complex, balanced, and sustainable development. Development management becomes indispensable for the weakest areas of the world. More than a development model, development management is the indication of a growth path and tools to support strategic planning, capable of reconciling the needs of the population with political needs.

Introduction

Economic and social growth should be based on the culture of a country, on the respect for local traditions, religions, and languages. The growth strategy must be the key to a balanced, independent, and long-term human development for a country. The definition of the general and specific objectives, resulting from a careful strategic analysis, must be the basis on which to build any development path.

The consideration of the actors involved and to be involved, as well as the knowledge of the essential skills in the short and long term, become necessary factors for the planning of a complex, balanced, and sustainable growth. The awareness of the need, by national governments, to achieve successes and results in the short term of the

legislature makes the planning of an integrated and shared development path even more complex.

The set of needs of a development path of a country characterized by a medium or low human development, together with an unavoidable lack of skills, make it extremely difficult for a government to define priorities also in the short term. A model of sustainable development which, however, also has a short-term impact must involve the population through national and international civil society, through the communities, associations, foundations, national, and international NGOs already working in the territory. The use of foreign skills for development has the great limitation of poor knowledge of the territory. On the other hand, local territories may lack the professional skills needed to design development.

The creation of a working group composed of local nongovernmental actors and international professionalism could overcome these two problems (knowledge of the territory and skills), ensuring a contemporary vision of the local area. Civil society and the international community must, however, support the government and not become a para-state. In fact, associations, foundations, and NGOs must not replace the governments, but must become an amplifier of the state's actions both at central level and on local realities. In other words, they must become a real support for the development of the country, reconciling top-down and bottom-up strategies.

Key Issue

As many empirical studies have shown on the development of disadvantaged territories, the need to link structural causes with the contingent causes of nondevelopment is one of the keys to the success of a strategy. In reality, what we propose, rather than a development model, is the indication of a growth path and of the management support tools: development management model (Sciarelli and Rinaldi 2017a).

The path that we indicate in this work is based on the idea of the development life cycle, which presupposes that a country has the intention

to develop and therefore wants to start its path of growth.

When the country expresses its intention to start a development process, it is positioned in the start-up phase of the process. At this stage, the main actors are the sustainable development state (SDS), the international community (IC) – through bilateral or multilateral plans and the commitment of intergovernmental institutions (II) – and nongovernmental actors (NGAs). The first ones are the fulcrum of the process, even if the international community plays an important role at this stage, having the task of providing material and immaterial resources to the state for the start of the development process and for the realization of a balanced yet steady growth.

The NGAs, on the other hand, have the task of implementing the strategies and acting as intermediaries with the population, involving them. In the start-up phase, there are five programming steps: strategic analysis (A), identification of strategies (S), planning (P), implementation (I), and control (C). These steps use tools from different management approaches, such as the methods of job splitting, Gantt and Pert Chart, Milestone, planning for output and outcomes, Experiment, Solar System HRM, etc. (Sciarelli and Rinaldi 2017a).

The country that intends to start its development path, therefore, uses the indicated method, and composes the five steps with its own distinctive characteristics. In this way, it creates a development path for the single country: country analysis (CA), country strategy (CS), country planning (CP), country implementation (CI), and country control (CC). As is evident from the figure, the SDS and the IC intervene in this first phase, having the same weight in the development process, while the NGAs still have a limited weight.

If, however, in planning a development process, governments were able to include individuals from civil society and foreign capital and skills in the start-up phase, they would also be able to achieve results in the short term without losing the cultural and social elements needed.

In the hang-on phase, however, the country has the main task of maintaining growth and creating development, gradually abandoning material and

immaterial resources from abroad. Civil society and the local population are starting to play an important role in the planning of development. In a two-way strategic approach (top down and bottom up), population involvement is a key factor. The SDS, with a slight support of international institutions, however, represents the pivot of the development program.

In this phase, the actors mentioned above, combining the method and the tools with the distinctive characteristics of the country, progressively make up four development areas (CA, CS, CP, and CI), leaving the control as an interphase to monitor not only the implementation of the plan but also the use of the methodology in the previous phases. Nongovernmental actors, therefore, in the second phase, acquire a fundamental role, becoming an actor able to help the definition of planning and to implement the planned development program. As the population adopts a development perspective, civil society, which has meanwhile become richer, healthier, and better educated, heads the process together with the SDS.

The national group, made up of public, private, and civil society actors, therefore becomes sufficient for its own development and progressively moves away from foreign aid, until it realizes a real self-development. In fact, at the end of the hang-on phase, the country moves toward independent development, whose main actors are the SDS and the NGAs. These together form the strategic and operational planning of the country, they always implement it in a synergistic way and fully realize the development process based on a joint top-down and bottom-up approach. In self-development, the steps provided by the method are infinite, as the duration of the phase itself should be infinite. The progression of the first four steps is the same as in the previous phase, with the control phase that is repeated throughout the programming process, but this is repeated “n” times and does not end in a single cycle, like what happens in our country.

During the hang-on phase, however, it is possible that the country will not be able to progress toward an increasingly autonomous development and that instead shows the need for international

aid. In this case, the development process of that country will crystallize in the formation of a social state, that is, of a state that needs to be helped by foreign capital and skills. The welfare stage has an indefinable duration, as it is interrupted when the intention to develop is reborn and therefore the development lifecycle starts again. In this stage, the method can still be used for planning, even if at the moment of hybridization with the peculiarities of the country it is generally transformed into traditional international cooperation plans.

All the characteristics of our development creation and management model, therefore, represent the method for planning and implementing development, without obviously indicating its contents.

There are therefore universal elements – the three stages of the life cycle, the method, the universal development objectives (MDG and SDG) and the composition of the actors, and many specific elements – the duration of the plans, the objectives, the choice of strategies, methods for achieving results, involvement and implementation, the system for obtaining the necessary funds for the development process, and the consequent control systems. The characteristics of the development management are therefore given by: the consideration of the human development as a whole, in balance between the areas, long lasting and independent; the hybridization of different approaches; the division into three temporally differentiated phases; a two-way approach, top down and bottom up; the presence of many different actors; strategic planning based on the use of tools from different systems of economic and social science; the growing separation of national and international public actors, which characterizes the growth of autonomy; the peculiar structuring of the development plans; the involvement of the population; and the need for a country to define its own particular development process.

Summary

Development management is an innovative growth management idea that can be of great interest, especially for weak areas of the world.

These areas are actors, often passive, of Western development models or in any case deriving from economically strong countries which distort their cultural and social essence, then managing, furthermore, to have no effectiveness on the territory. In fact, the development models adopted by the international community often lead to welfare and not to self-development. Development management aims to achieve balanced human development that can truly realize the emancipation of weak areas from the strong international community (CI). The proposed idea is based on a development management divided into three phases, in which the second, hang on, turns out to be the decisive one, being able to decree the entry into a self-development system or bring the territory back into the welfare model. The leitmotiv of the development management idea is the possibility of making the areas autonomous, providing for an economic and organizational accompaniment of the IC in the first phase, a bottom-up involvement of the population and NGOs in the second phase, and the definitive departure from accompaniment of the international community in the third phase of self-development.

[Country human growth plan](#)

Definition

The development of a country cannot be confused with its economic growth. A country that grows economically but is made up of illiterates, for example, would be so unbalanced that it could not make the economic growth achieved sustainable and generalized. Income differentials are therefore only one of the variables. The health of a population and its education, in fact, are necessary variables for the balanced and sustainable development of a country.

Introduction

The development of a country cannot be confused with its economic growth. A country that grows economically but is made up of illiterates, for example, would be so unbalanced that it could not make the achieved economic growth sustainable and generalized. Income differentials are therefore only one of the variables. The health of a population and its education, in fact, are necessary variables for the balanced and sustainable development of a country.

Key Issue

Understanding the problems of a territory is often a requirement for a full understanding of the viable solutions.

The most frequently followed paths in the strategic plans include: a phase of analysis of the state of the art; the definition of the vision; the definition of the general objectives; the indication of the actors involved and in some cases of the management modalities of the human resources involved; the budget; and the monitoring and control activities.

Internal and external communication is almost always lacking and very often, within the plan, we find no indications of budget and human resources. We also find no specific objectives in the strategic plans. Together with monitoring, specific objectives are often postponed to short- and medium-term plans.

Another element that links the strategic development plans is a reduced time frame. This often derives from the duration of the legislatures and from political stability (or instability). Analyzing the structure used today on average for strategic planning of development is a fundamental step to understand the limits and propose tools to improve its effectiveness.

It is possible to found various types of development plans (Sciarelli and Rinaldi [2017a](#)):

- Long-term strategic plans (10/30 years), defined by the current government, adopted and

Development Program, Fig. 1 Development Chinese boxes (Sciarelli and Rinaldi 2017a, b)

- Readapted by other governments
- Medium-term strategic plans (4/5 years), defined by the government and concluded in the government legislature:
 - Strategic sector plans (10/5 years), defined by the government and the competent ministry and then adopted and readapted by other governments.
 - Short-term operational plans (3/1 year), defined by the central government and by local administrations and implemented by them.

However, the territory is not a company that can realize its strategic plan in five years. The territory needs time. In transformation or transformable areas, the development path is long and the desired human development objectives cannot be achieved in three years. On the other hand, it is also true that territorial strategies are linked to political power and therefore generally are constrained to a limited time. These two elements cannot be reconciled with a serious path of human development. Unraveling and redoing the plans several times over time, like the canvas of Penelope, it is difficult to achieve a real and persistent development. Political instability is indeed one of the main obstacles to real development. The other anomaly is that, even when studying the “operational”

plans, that is, the annual, three-year ones or those concerning a specific activity plans, the results are postponed to other operational plans that will then take care of the implementation of the program.

All this structure creates a system of Chinese boxes (Fig. 1) that never allows to get to the implementation of the action and above all that, in the confusion, they lose the traces of the responsibility.

With such a system, there will always be a plan that was created, for example, to improve the education of tribal areas but then the implementation of this plan will be lost among the Chinese boxes of strategic planning, not allowing to understand the responsibility and to monitor the effects of the strategies themselves.

The truth is that one of the main problems is the transition from planning to implementation. As we have seen, all governments have strategic plans and operational plans, but in many cases there are no traces of programs dedicated to implementation, except in specific cooperation plans or linked to international funding. Frequently, the implementation of the strategic plan presented, subdivided in single activities, is then entrusted to civil society, nongovernmental bodies, volunteers, and international projects. Often, therefore, the strategic plan, even if it is articulated in hundreds of pages, represents more a strategic

orientation, more a declaration of intentions than a real long- or medium-term work program (Sciarelli and Rinaldi 2018).

Another emerging element is that the strategic plan is a formal necessity rather than a real need. In fact, now all countries to access funding and international competences must necessarily show a direction and structural capacity not only to develop a strategic plan, but also to complete it.

Summary

In our opinion, the main problems of country development planning are the proliferation of development program, the frequent overlapping, the poor implementation of the same, and the frequent impossibility of identifying the responsibility for the success or failure of the program. All this makes up the model of the Chinese boxes in a natural way, which also graphically represents the situation of the typical programming of the countries.

Synonyms

[Corporate scandals](#); [Emission scandal](#);
[Emissiongate](#)

Definition

Dieselgate is the popular name for the high-profile Volkswagen Group emission scandal that began in September 2015 following the discovery of software the company had installed in diesel engines since 2009 in order to let these engines perform favorably when it comes to harmful nitrogen oxide emissions in laboratory tests when compared to actual road tests and its publication in the media. The scandal resulted in a severely damaged reputation of the German car maker as well as severe personal, legal, and financial repercussions. Also, Dieselgate led to a change in corporate strategy at Volkswagen Group toward a long-term focus on developing electric vehicles. In the years following the original scandal, Dieselgate has become a category name for similar corporate scandals in the automotive sector, which appeared to be the rule rather than the exception.

Corporate Scandals

As long as there have been companies, corporate scandals have existed – the mere fact that behavior can be compromised, implies that, under certain circumstances, it will. Corporate scandals can be seen as a form of organizational crisis, which can be defined as “a low-probability, high-impact event that threatens the viability of the organization and is characterized by ambiguity of cause, effect, and means of resolution, as well as by a belief that decisions must be made swiftly” (Pearson and Clair 1998). Corporate scandals hence tend to imperil the continuity of business as usual and oftentimes an outright threat to the existence of organizations and, by implication, demand a swift and profound response to mitigate the effects and remedy the situation. As DeMott (2012, p. 468) writes, “natural disasters, political upheaval, bank panics and other financial crises, and massive technological failures may all precipitate crises for corporations and other organizations when unlikely risks materialize.”

Hoffman’s (1999) general description of a scandal as a public manifestation of misconduct suggests that behavioral irregularities and unethical practices are a root cause of scandals (cf. Zona et al. 2013). Indeed, scandals may be caused by violations of norms and values, either personal or social, including the rule of law, expectations that are held by corporate stakeholders or broader society, explicit or implicit corporate codes, and one’s principles. Especially in the context of an era in which corporate social responsibility (CSR) has become a focal point of attention for companies, scandals may easily occur as a consequence of companies comprising their own ethical standards and CSR claims.

The effects of a corporate scandal may be substantial; it can damage a company and its direct and indirect stakeholders in different ways. Examples of damage incurred by a corporate scandal include a tarnished reputation, plummeting stock value, legal, and financial punishment (Karpoff et al. 1999; Sullivan et al. 2007). However, individuals, including directors, managers, and employees, may also directly experience the effects of a corporate scandal,

for instance, through losing their position within the organization or through a compromised ability to find another equivalent job (Desai et al. 2006). In addition, corporate scandals may have societal effects, such as effects related to economic performance and environmental consequences, and political effects, including the need for establishing costly government bail-out schemes leading to political debate, lawsuits against corporate executives that may involve high-political figures, and pushes for tighter regulations.

It should be noted, however, that it is not its mere effect that makes the scandal a scandal, but also – and perhaps notably – unethical behavior that leads to that. This may include intentionally doing or not doing things, or negligence, even without intent.

Dieselgate: A Prominent Example of a Corporate Scandal

A number of poignant examples of corporate scandals have shaken the international business community over the last few years (Painter-Morland 2008, p. 1), including financial, accounting, and reporting scandals (e.g., Enron, WorldCom), product scandals (e.g., Danone), and environmental scandals. (e.g., BP, Shell). However, “no business scandal has precipitated greater interest in the ethics of business than the spectacular rise and precipitous fall of Enron,” Willmott wrote in 2011 (p. 96).

Obviously, no one could foresee at that point in time that 5 years later Volkswagen Group would be in the limelight with what appeared to be a landmark corporate scandal, popularly called Dieselgate. Hitting the presses in September 2015, Dieselgate became an emission scandal following the discovery of software that the company had been intentionally installing in order to deceive laboratory emission tests. Reinforced by the widespread media coverage of it, the malign ingenuity and pervasiveness of this ethical misconduct by one of the world’s largest companies and the fact that the company has made explicit sustainability claims regarding its products would

make Dieselgate a category name for similar corporate scandals in the automotive sector, which turned out to be the rule rather than the exception.

The Dieselgate scandal resulted in a severely damaged reputation for the German car maker as well as severe personal, legal, and financial repercussions. Also, Dieselgate led to a change in corporate strategy at Volkswagen Group, pivoting toward a long-term focus on developing electric vehicles.

The Unfolding of Dieselgate in a Nutshell¹

When Volkswagen Group issued its ‘Strategy 2018’ in 2007, it was clear that an underlying ambition of this strategy was to become the largest car manufacturer in the world. In addition, the strategy clearly set forth that sustainability was an important principle in achieving this strategy, taking responsibility for developing fuel efficient cars and substantially reducing harmful emissions.

In September 2015, the United States Environmental Protection Agency (EPA) confirmed that Volkswagen Group had been installing software (the so-called defeat or deceit device) in its diesel engines since 2009 with the objective of letting them perform favorably when it comes to NOx emissions in laboratory tests when compared to actual road tests. The findings of the EPA resulted from a study by the International Council on Clean Transportation that was commissioned in 2014 by the California Air Resources Board, aiming to investigate discrepancies in emissions between US and European car models. It appeared that the so-called clean diesels would emit up to 40 times more NOx in real-world driving and that the software was installed in some 11 million cars worldwide in model years 2009–2015. When the media quickly picked up on these results, Dieselgate was born.

Subsequently, authorities in several countries started to investigate Volkswagen Group. The company’s stock price plummeted in the days following the news, then CEO Martin Winterkorn (who was charged in the United States with fraud and conspiracy in May 2018) and several key managers were suspended. In April 2016, Volkswagen Group announced to spend €16.2 billion on remedying the emissions issues and the company planned to refit the affected vehicles as part of a recall campaign. In January 2017, the company pleaded guilty to criminal charges and agreed on a legal statement that set out how engineers had developed the so-called defeat devices, since diesel models could not pass US emission tests without them, and deliberately sought to conceal their use (Leggett 2017). Some months later, in April 2017, a US federal judge ordered Volkswagen to pay a criminal fine of US\$2.8 billion for rigging diesel-powered vehicles for the purpose of cheating on government emissions tests.

Analyses and reconstructions reveal that the occurrence of Dieselgate can be attributed to various causes. By the end of 2015, the company admitted that the scandal was caused by an entire chain of failures – it was seen as “the result of a combination of individual misconduct and mistakes in one part of the business but also flaws in company processes and a tolerance of rule-breaking” (Ruddick 2015). Later, former CEO Matthias Müller stated at the Volkswagen Group annual media conference and investor conference that the fraud was the work of lower-ranking employees, denying the involvement of members of the then management board of the company. Kerler (2018) writes that as politicians have been too lenient in their support for car manufacturers, they, too, can be seen as a cause of Dieselgate.

Responses to and Effects of Dieselgate

The Dieselgate scandal has had many effects and has triggered many responses, varying from the level of the company level to the academic world. Without pretending to be exhaustive, the following points provide an illustration of the various responses to and effects of Dieselgate.

¹ The information presented in the remainder of this paper is partly based on the Wikipedia pages in the Dutch and English language about Dieselgate.

- Volkswagen Group has clearly suffered from a tainted reputation, and the Dieselgate label will always be associated with the company. Next to its stock value falling with around one-third within a couple of days, the company also faced large fines and has had to pay a substantial compensation to authorities and clients. For instance, Volkswagen Group has been offering vouchers and trade-on bonuses to US clients and has committed to buy back nearly 500,000 2.0-liter vehicles, as part of a settlement in North America sales (Ewing 2016). While its US car sales dropped around one-quarter by the end of 2015 (Welch and Hull 2015), car sales in other countries, however, were hardly or not negatively affected by the Dieselgate scandal. In fact, due to aggressive marketing efforts, sales in November 2015 in South Korea increased with some 66 per cent compared to the previous year (Nam 2015).
- Dieselgate resulted in a host of legal consequences for Volkswagen Group and the scandal touches upon several legal issues on national and supranational level, including laws of unfair competition, contracts, torts, administrative, and criminal law. In addition, many private disputes have been settled (Nemeth and Morais Carvalho 2017: 35).
- From a corporate strategy perspective, Dieselgate can probably be seen as an additional impetus for the development of electric vehicles at the expense of combustion engines. In June 2016, Volkswagen Group announced plans to invest heavily in the production of electric vehicles. That month, Matthias Müller, the successor of the demitted-down CEO Martin Winterkorn, predicted that Volkswagen would introduce no less than 30 fully electric cars over the next 10 years, expecting that electric vehicles would account for around 25 per cent of the company's annual sales by 2025. The company said it planned to fund this development by making its operations more efficient and through cutting costs. Müller said that these changes would "require us – following the serious setback as a result of the diesel issue – to learn from mistakes made, rectify shortcomings, and establish a corporate culture that is open, value-driven, and rooted in integrity" (BBC News 2016). In November 2018, the Volkswagen Group published its plan to spend €44 billion in the development of electric, autonomous cars by 2023 (Taylor 2018). Also at the end of that year 2018, the company has been reported to say that its next generation of combustion cars will be its last, pursuing a radical shift to electric vehicles (Rauwald and Sachgau 2018).
- There were industry effects of the Dieselgate scandal as well. Research by Fracarolli Nunes and Lee Park (2016) showed that the fraud spread to surrounding companies within the automotive industry and through the supply chain. This market contamination is estimated at a cost of around US\$6.44 billion for American firms alone. Also from an industry perspective, transgressions of other car manufacturers have been reported since as Dieselgate raised awareness of the pollution caused by "clean diesels" and has increased scrutiny of combustion engines in general. Emission tests in multiple countries have shown that many cars fail to comply with emission regulations, while a 2016 French government report concluded that 4/5 of 86 different cars investigated failed to comply with emission laws, research by ADAC in that same year showed that 38 out of 40 tested diesel cars failed an NOx test since 2016.
- Obviously, the emissions that cars actually emitted but were covered up by the misleading of emission tests have had effects on public health and the environment. In the United States, the number of premature deaths caused by the fraud has been estimated to be 59 (Vaughan 2015). The actual impacts in Europe are bigger because of much greater popularity of diesel cars compared to the United States as well as a higher density of the population. Here, it has been estimated that over 44,000 healthy life years were lost (Oldenkamp et al. 2016). Axel Friedrich, a cofounder of the ICCT

was reported to say about Dieselgate that “it’s not just fraud – it’s physical assault” (Ewing 2016).

- Dieselgate has had multiple consequences from a political perspective. Besides the fact that lawsuits against the company suggest that politicians of German regional government that held positions in supervisory roles are also responsible for what happened at the company, Dieselgate also led to a push for tighter emissions regulation. However, in June 2016, documents that were leaked to the press indicated that in 2010, officials for the European Commission had already been warned by their inhouse science team that at least one car manufacturer was possibly using a NOx-related defeat device in order to bypass emission regulation. Member of the European Parliament Kathleen Van Brempt, then chair of the investigation of the scandal, said she found the documents shocking, and these raised serious concerns with regard to the future of commission officials: “These documents show that there has been an astonishing collective blindness to the defeat device issue in the European commission, as well as in other EU institutions” (Neslen and Harmsen 2016). In an article for The Verge, Kerler (2018) cites Ferdinand Dudenhöffer, a professor of Automotive Economics at the University of Duisburg-Essen, saying that “German politicians always thought they were helping the car industry by being soft on regulations and keeping their eyes shut.” As a consequence, most German voters now hold the opinion that the government was too lenient on Volkswagen as well as on other German car manufacturers, causing political turmoil.
- From an academic perspective, Dieselgate has also spawned a host of analyses in academic literature addressing topics including the effectiveness of regulations and economic incentives in the context of environmental policy (Zachariadis 2016), reflections on legal implications (Di Rattalma 2017), its detrimental implications for the wider market (Robertson 2017), and criminological perspectives (Spapens 2018).

Description/Definition

The corporate world is ever changing and evolving; there are emerging economies; digital technology is transforming the workplace; and corporates are becoming increasingly complex. It is not surprising therefore that corporate governance “the system by which corporations are directed and controlled” (Cadbury 1992) is also changing. Corporate governance has been narrowly defined as a means for protecting shareholders’ interests; however, in today’s operating environment whereby online media is constantly providing a stream of information on the corporates which we invest in, work for, and purchase from, it is not surprising that the sole objective of corporate governance systems, being the protection of shareholders’ interests and rights, may no longer be the case.

Corporate governance can be redefined more broadly as “the system of rules and regulations and practices by which we hold managers accountable and responsible for whatever performance society expects” (Haspeslagh 2010). This definition suggests a move toward a holistic stakeholder-driven approach to governance which embraces the fact that corporates have legal-, contractual-, social-, and market-driven responsibilities to non-shareholder stakeholders, including employees, investors, creditors, suppliers, local communities, customers, and policy makers. Corporate social responsibility (CSR) activities and disclosures are the main way in which corporates address these obligations as it involves the “integration of an enterprise’s social, environmental, ethical and philanthropic responsibilities towards society into its operations, processes and core business strategy in cooperation with relevant stakeholders” (Rasche et al. 2017, p. 6).

Boards of directors are the zenith of internal decision control systems of corporations and are therefore accountable not just in terms of financial performance to investors but also in terms of society as a whole’s expectations that this will be achieved in a sustainable way. The board of directors is in charge of the management of the business; they make the strategic and operational

decisions and are responsible for ensuring that all statutory obligations are met. They also need to do so in a sustainable way, and therefore CSR activities need to be managed. This chapter details director’s broad responsibilities within corporations in relation to CSR strategy and nonfinancial disclosures as well as addressing the need for them to continuously engage with internal and external stakeholders.

Director’s Responsibilities

The classical economic argument presented by capitalist Friedman is that “the business of business is business” and that management has one responsibility, and that is to maximize returns to shareholders, with social issues being resolved by the free market system and or governmental intervention. However, given the size, power, and expertise contained within corporates, it is increasingly argued that this is no longer the case and that they have a duty to act in the best interests of stakeholders as a whole. Indeed some believe it is the very purpose of the corporate to serve as a vehicle for coordinating stakeholders (Evan and Freeman 1988). Moreover, some global bodies have taken the view that information on CSR is important for investors. They have been promoting the inclusion of information on environmental, social, and governance (ESG) in reports aimed at investors. For example, in a recent publication *Fiduciary Duty in the twenty-first Century* (2015) by the UN Global Compact, UNEP Finance Initiative, Principles for Responsible Investment, and Inquiry into the Design of a Sustainable Financial System, it was concluded that “Failing to consider all long-term investment value drivers, including ESG issues, is a failure of fiduciary duty” (Sullivan et al. 2015, p. 9).

It is widely considered that in running corporates on behalf of the owners, directors have a number of “fiduciary duties” to the owners. Fiduciary duties have been developed through case law and are then typically codified in corporate law. For example, in Britain, the Companies Act 2006 states that a director:

- Only acts within the powers granted by the corporate's constitution
- Has a prime duty to promote the corporate's success (unless insolvent)
- Exercises independent judgment
- Exercises reasonable care, skill, and diligence in his/her role
- Avoids conflicts between his/her role and his/her personal interests
- Does not accept benefits from third parties which arise from his/her role
- Always declares to other directors his/her personal interest in any transaction or arrangement which the corporate proposes to enter into

There is a focus, of course, on protecting shareholders' interests; however the Companies Act 2006 aims to make a significant contribution to the corporate governance system in the UK by embedding in statute the concept of "enlightened shareholder value." The Act legally mandates shareholder value but with the proviso that it should be "enlightened" by specific statutory requirements designed to promote an "inclusive" approach toward the interests of stakeholders and to encourage a long-term view to be taken of corporate investment. Section 172 of the Companies Act (2006) places an obligation on directors to "have regard to" a range of other stakeholder interests in pursuit of their general duty "to promote the success of the company."

The financial statements are published as part of a corporate's annual report. Included within the annual report is a strategic report. This report supports the financial statements and, in addition, typically contains nonfinancial disclosures which should provide shareholders of the corporation with information that will enable them to assess how the directors have performed their duty to promote the success of the corporation, while having regard to the matters set out in section 172. The contents of the strategic report are covered under the Companies Act 2006 s414(C), which requires: a description of the corporate's strategy, objectives, and business model; an explanation of the main trends and factors affecting the corporate; a description of its principal risks and uncertainties; and an

analysis of the development and performance of the corporate, including key performance indicators. In making these disclosures the corporate must provide information about the environment, employees, social issues, community impact, human rights, and anti-corruption and anti-bribery matters if material. There is also a requirement to include disclosures on gender diversity across the workforce.

In addition to the disclosures required in the strategic report, the Department for Business, Energy & Industrial Strategy (BEIS) has published regulations which implement the EU nonfinancial reporting directive 2014/95/EU on disclosure of nonfinancial and diversity information by certain large undertakings and groups in their management reports. These regulations will apply to the financial years of qualifying "Public Interest Entities" (PIE) (broadly any corporate with over 500 employees) with reporting beginning on or after 1 January 2017. The aim of the regulations is to recognize the importance of nonfinancial information in identifying key sustainability risks and in an attempt to increase investor and consumer confidence.

The new regulations expand on the contents of the strategic report with further disclosures relating to the business model, principal nonfinancial risks and nonfinancial key performance indicators also being introduced, as well as specific bribery and corruption disclosures. Details on diversity policies including the age, gender, and educational and professional background of board members will also be required to be disclosed as part of the corporate governance statement.

The corporate governance statement is another form of nonfinancial disclosure in the annual report. The contents of this statement are driven by the UK Corporate Governance Code (2018) with which UK-listed corporates must comply or, where they do not comply, explain to investors why they do not. The UK Corporate Governance Code has stakeholder management and CSR at its heart, and Section 1 "Board Leadership and Company Purpose" contains the following principles:

- A. A successful corporate is led by an effective and entrepreneurial board, whose role is to

- promote the long-term sustainable success of the corporate, generating value for shareholders and contributing to wider society.
- B. The board should establish the corporate's purpose, values, and strategy and satisfy itself that these and its culture are aligned. All directors must act with integrity, lead by example, and promote the desired culture.
 - C. The board should ensure that the necessary resources are in place for the corporate to meet its objectives and measure performance against them. The board should also establish a framework of prudent and effective controls, which enable risk to be assessed and managed.
 - D. In order for the corporate to meet its responsibilities to shareholders and stakeholders, the board should ensure effective engagement with, and encourage participation from, these parties.
 - E. The board should ensure that workforce policies and practices are consistent with the corporate's values and support its long-term sustainable success. The workforce should be able to raise any matters of concern.

Integrating CSR Theory into the Boardroom

From the guidance outlined above, it appears that directors need a mechanism for integrating CSR activities into their corporate's strategy and operations; however, there is little guidance academically or practically on how to do this effectively. Many corporates engage in "stakeholder mapping" whereby stakeholders are identified and categorized according to different levels of engagement. Mapping of the stakeholder is usually done according to the level of interest that they have in the corporate's activities and the level of influence they have over the corporate's activities. The premise being that you cannot fulfill every stakeholder's expectations and directors should focus on satisfying expectations of the stakeholders who have a high level of interest and influence relating to the project. On the other hand, stakeholders having a high level of interest but low influence need to be merely kept informed

of the project status (Mitchell et al. 1997). Often this mapping is a visual exercise, and many corporates use technology to produce sophisticated continuous monitoring and reporting on stakeholder management.

Indeed, technology can be used in the integration process by communicating with stakeholders on CSR activities and generating live feedback through tools such as websites and social media. This ability to enter into "strategic conversations" has led to a substantial rethink on corporate communication recognizing that the dialogue can play a formative role in constituting, altering, and regenerating organization, termed communication constitutes organizations ("CCO") (Christensen and Cheney 2011). Under CCO, communication is a textual representation of how the corporate's strategy can evolve by iterative, continuous negotiation between corporates and society. When the negotiation has resonance with other corporate logics, such as value creation, then co-construction of the CSR agenda may result (Cooren et al. 2011). The first step a corporate has to take to enter dialogue and engage in CCO is providing the opportunity for stakeholders to do so across communication platforms such as corporate reports, websites, and social media.

Generate Internal "Buy In" for CSR

As well as integrating external stakeholders into the CSR process, CSR must be embedded fully into the decision-making of the corporate as a whole in order not to attract criticism for not "walking the talk" and considered a sign of bad management in general. In order for CSR to permeate into all aspects of the corporate's operations, there must be a combination of "hard wiring" and "soft wiring" approaches to its integration (de Wit et al. 2006). Hard wiring is the grounding of CSR in corporate systems and protocols, for example, employee selection criteria, codes of conduct, and CSR requirements as part of product development and social due diligence on new supplier relationships. Soft wiring on the other hand is the infusion of CSR into the culture of the corporate, for example, senior managers

acting as role models in relation to sustainable business practice, sustainability being a core cultural value, staff opinion surveys, socially responsible supplier practice, etc. This all requires constant communication, training, and advocacy throughout the corporate from the top down so as to permeate all decisions being made within the corporate.

Evidence indicates that management has an important impact on the outcomes of CSR projects (Waddock et al. 2002). The values of top management have an imprint on the corporate, which in turn influence decision-making processes, stakeholder engagement, and corporate social performance. However, even in a corporate with formalized CSR policies, procedures, and tradition, managers hold different and non-convergent views on CSR activities (Pedersen and Neergaard 2009). The alignment of managerial perceptions is an impossible task as they will always be influenced by a number of variables such as age, gender, tenure, education, religion, and so on. It can be argued that this diversity of thought is necessary to drive positive change through conflicts of opinion, but this tension needs to be carefully managed.

There are indications that CSR is gradually becoming infused and embedded in corporate governance with CEOs taking a leadership role for CR issues. Boardrooms are increasingly creating dedicated CSR subcommittees of the board which are focused on formulating CSR strategy, reviewing the progress against CSR key performance indicators, monitoring CSR compliance and risk management, and keeping the board up to date with CR issues (Spitzeck and Hansen 2010). It could be argued, however, that the use of CSR committees is poor CSR governance practice as it might isolate CSR issues from wider business strategy and operational decision-making, i.e., emphasizing the “bolt on” criticism of CSR activities.

Summary

Corporates which engage in CSR activities fall on a spectrum from “compliance strategy,”

whereby the corporate observes regulations and controls and measures predefined specific aspects of CSR performance through to an “integrated strategy” whereby CSR is underpinned in the core values of the corporate. The integrated strategy is based on the values and ethical decision-making of all the members of the corporate who in turn form its overall corporate culture (Crane and Matten 2004). The significance of boardroom leadership as a driver for CSR activities and corporate change with regard to sustainable practice cannot be underestimated; “top leadership has to believe and walk the talk. Staff and other stakeholders need to hear their leaders explain regularly what responsibility and sustainability means for the corporate, why it is important and how it is integrated with corporate purpose and strategy: what some people call ‘tone at the top’” (Bhalla 2013, p. 577). This should be explicitly linked to the stated values of the corporate as until it does, the true business case for CSR activities will never be achieved.

 Diversity management

Definition

Disability management refers to a management orientation that focuses on people with disabilities and their enhancement, with the aim of adapting organizations of the socioeconomic systems (i.e., institutions and companies) and allow them and manage their needs (Mittler 2015). Disability is a holistic theme crossing different disciplines (Shakespeare 2014). According to the Convention on the Rights of Persons with Disabilities (UN 2006) it is to be understood as the result of the interaction between impairments and social, attitudinal and environmental barriers that hinder or limit participation (EC 2017). The Convention promotes the actions aimed at improving educational, training, and professional opportunities to avoid possible exclusion or marginalization of disable people from the work and the society as a whole. It represents a pillar in countries that have adopted it having to apply the Convention through measurable and accountable actions to the national community. Article 1 of the UN Convention takes over the World Health Definition (WHO 2001, 2011) and establishes that people with disabilities are those who present lasting physical, mental, intellectual, and sensory impairments that in interaction with barriers of different nature can hinder their fullness and participation in society on an equal basis with other people. This definition brings a novelty because it considers the disable people “linked to” their environment. Therefore, the problems related to disability no longer affect disables at an individual level but also the cultural and socioeconomic environment (Angeloni 2013).

Introduction

According to the first Report of the World Health Organization (WHO 2011) the estimated number of people with some form of disability would approach one billion. It counts for about 15% of the population worldwide, of which 80% is located in developing countries (Ottawa Charter for Health Promotion 2012).

Disability management has developed since the mid-1980s, especially in North America, while in Northern Europe it was introduced in the last decade. Some countries, such as Germany, Switzerland, the Netherlands, the USA, the UK, and Canada, are at the forefront, while others (China and Japan, Italy, and France) are on late in institutionalizing the disability management (Loyalka et al. 2014). Namely, in Italy the legislation ratified the Convention with Law 18 in 2009. The first initiatives date back to the 1990s (Torre 2007; La Torre et al. 2009). Currently, AIDIMA (Italian Association of Disability Manager) and SIDiMa (Italian Society of Disability Manager) are strongly committed in supporting the research and promoting the culture of disability management, as well as in training specialized professional figures. Both associations also collaborate with several actors (universities, businesses, public institution) on the national and international arena (the European Association of Service Providers for Persons with Disabilities, among others) with the aim to support the activity of disability managers (Mattana et al. 2011; Ferrucci 2014; Ravicchio et al. 2015; Mattana 2016).

Among the international standards aimed to protect the rights of persons with disabilities the UN Convention emerges decisively in 2006 (Baratella 2009; Foggetti 2017). Accordingly, many countries have adapted their legislation (Fondazione Serono 2016): in the United Kingdom by the Equality Act (2010), in France by the Loi Handicap was promulgated (2005), in Spain by the combined provision of the Liondau (2003) and the Ley de Dependencia (2006), among others.

In the last decade, conferences, projects, and training and educational initiatives on disability management have multiplied, attracting the attention of the scientific and business world. Several journals contribute to develop the international debate, including *Journal of Applied Research* or *Journal of Intellectual Disabilities*; *Neurological Science*; *Journal of Preventive Medicine and Hygiene*, among others.

The disability management deepens the diversity management logic (Cuomo and Mapelli 2007;

Nota et al. 2014; Konrad et al. 2016) by inspiring human resource management and companies' strategies, because in addition to workers or customers/users, people with disabilities are also owners, lenders, and suppliers (Migliaccio 2017).

Disability management attracts the interest of several scholars belonging to both managerial and economics fields (O'Brien 2013; Twigg 2005; Hancock and Pudney 2014; Silva and Vall-Castelló 2017). Moreover, the microeconomic-corporate approach has been investigated, even if diversity management was prevailing in attracting the attention of the international debate (Lu et al. 2015; Janssens and Zanoni 2014; Li et al. 2016; Holck et al. 2016).

Key Issues

Whoever elaborates in theory and in practice the diversity management strategies is the diversity manager, who can be internal or external to the corporate structure. The disability manager, more than a profession in itself, can be considered an additional "competence" aimed to integrate pre-existing professions (i.e., architect, lawyer, social worker). The role of disability manager can also change depending on different work contexts (private businesses, local authorities, schools, hospitals, etc.).

As a consequence, there is a need for transversal skills and training activities addressed to entrepreneurs and human resources managers in order to allow them to acquire the necessary skills and capabilities and ensure them that the inclusion of people with disabilities is a high-quality work experience for all employees and an opportunity for a company's growth and innovation.

Drawing from empirical studies disables' recruiting appears as a crucial phase (Nota et al. 2014). Organizational culture is among the factors that affect the recruitment and inclusion of disabled people in the workplace (Zappella and Dovigo 2014). Moreover, the employers' attitudes change according to different types of disabilities and are positive if they had previous positive experiences. Accordingly, disability management

policies are successful when they improve relationships and the quality of worker's productivity (Konrad et al. 2016). However, disability management is not yet a widespread practice despite companies show a growing interest in the role of disability managers and the beneficial effects of such practices (La Torre et al. 2009).

Some studies (Ravicchio et al. 2015) point out that the disability manager plays a key role in implementing smart working practices that favor inclusion and positively affects growth and organizational change. Therefore, it is important to identify and disseminate best practices and innovative labor policies. In this respect one can argue that there is a need to strengthen dialogue between companies, public and private recruiting services, training institutions, universities, to promote the education of future managers through postgraduate curricula and masters on disability management. One can find virtuous examples of disability management adopted by multinational companies, that in recent years have promoted good practices and dissemination events that are gradually spreading among small and medium-sized enterprises (SMEs), especially in organizations that have obtained certifications such as the SA 8000. In some countries (such as Italy, among others) tax incentives have been introduced to enhance diffusion among SMEs (i.e., tax reduction for productivity bonuses, partly converted into corporate welfare policies).

Future Directions

Disability leads us to reflect on what is fundamental in the personal and professional life. It claims for an economy for inclusion. A relevant contribution to the interpretation perspective of disability is offered by the disability studies, developed mainly in Anglo-American context, which underline the active role of people disabled in the process of transformation of society in an inclusive direction. Rather than focusing on the "disability issues" it is necessary to emphasize the value of the "person with disabilities." The welfare logic places people with disabilities in public or non-profit companies. However, this could not be

enough. A new economic and cultural approach should drive management's choices toward a sustainable growth capable to consider all people as a key resource, including people with disabilities. To do this, education plays a central role. For disabled education is to be conceived as a pillar of a life project built on self-determination and projected toward autonomy: a perspective of life possible only outside of a medicalized reading and disability assistance – conceived as a disease – and which appreciates disabled as resources and makes the potential of people with disabilities visible both as individuals and as groups capable of exercising a political role and social. A different interpretation of disability is introduced by the bio-psycho-social model of the ICF – International Classification of Functioning, Disability and Health (WHO 2001). According to this disability depends on several interrelated factors: physical conditions and biological endowment, contextual factors (environmental and personal factors). The ICF promotes a holistic approach and is aimed to study and intervene in individual and social contexts to guarantee an overall quality of the individual's life and overcoming the contrast between the medical and social approach, thus attributing to disability and handicaps distinctive meanings.

Within the international debate, a theoretical construct aligned with the principles of complexity and dynamism of the ICF is the Quality of Life approach (Schalock and Verdugo Alonso 2002) that "synthesizes a plurality of dimensions of people's lives from physical well-being e material to emotional well-being, from personal development to self-determination, from personal relationships to social rights and social inclusion" (Giaconi 2015, p. 13).

Within the 2030 Agenda for sustainable development (UN 2015) the paradigm of inclusion based on human rights permeates all 17 objectives, in order to free up people with disabilities from the still predominant invisibility condition. The paradigm of inclusive growth mirrors the development policies of the Convention on the Rights of Persons with Disabilities. European governments have become progressively more aware of the strategic importance of the

implementation of initiatives that address the issue of disability, although it is necessary to underline that more efforts should be spent, in particular in developing countries. While in certain cultural contexts the formal recognition of the rights of disabled has been achieved, to recognize a role social in its multiple dimensions, even in economics still represents a challenge.

An inclusive approach based on the valorisation of disability should be strengthened. Disability recalls the reality, often eluded, of the fragility of human existence. Recognizing and accepting this fragility is a necessary condition to pursue an inclusive economy. In the business context the basic problem is cultural in nature, because the enhancement of diversity and the consideration of diversity management among business strategies pass through a broader vision of growth and the achievement of long-term objectives. First, it requires the entrepreneurial and managerial commitment; second it claims for the adoption of a structured approach, affecting the recruitment and training activities, as well as the rewards and promotions systems. In Italy, despite the lack for an institutional framework on disability and diversity management, the Italian Society of Disability Managers supports for years several high-level training courses since there is a strong demand for specialization on these issues. The training activities must be diversified depending on the sector and nature of the firm. Moreover, some university (i.e., LUMSA) have set up Master to provide specialized knowledge and skills for the management of disability and diversity in companies (both private and public companies), business consultants, professionals, trade unions, and welfare plan designers. The disability managers are increasingly gaining momentum. The integration of two functions (welfare manager and disability manager) could render the role more effective since it allows a manager to operate in both private and public companies when they are involved in inclusion and enhancement programs for diversity and well-being in the workplace. The practical and cultural originality of the proposal lies precisely in the positioning of the expert in disability and diversity in the context of the broader skills on welfare in the company, with a view to the persons' welfare.

Summary

Diversity management manifests in a set of transversal business practices – under the “umbrella” of the corporate social responsibility policies – that affect the corporate culture, the strategy, the financial and control management system, the operational activities, as well as the system of relations with the stakeholders and the company reporting (Angeloni 2013; D’Amato 2009; Metallo et al. 2009; Migliaccio 2016). The growing attention paid by policy makers, businesses, and institutions to diversity management is attributable to the increased complexity of society, characterized by a multiplicity of social, cultural, and individual subjectivities tied to gender, age, ethnic origins, disability, sexual orientation, personality characteristics, cognitive styles, level of education, background, etc. In such a context disability management is conceived as a proactive strategy aimed at identifying and solving the factors that prevent people with any type of disability from accessing work (Geisen and Harder 2011). While diversity management consists in practices that an organization implements to create an inclusive climate and an organizational culture (Oberfield 2014), aimed to allow workers attitudes and capabilities flourish and ensure growth and success of their personal and professional paths, disability management is not only limited to a process or to a set of procedures (O’Brien 2013; Sabharwal 2014), but it represents a professional activity which considers all the relational aspects (personal contacts and interactions) that contribute to the success of disability management. Currently disability strategies are often implemented as a reaction to the problems of a single person or an organization, while empirical studies suggest to consider such problems in advance through appropriate policies and procedures for overcoming and preventing them (Geisen and Harder 2011). Namely, workplace disability management concerns all cases of disability from personal and congenital disabilities to those acquired during the working period (ranging from accidents to chronic-degenerative diseases). In this sense, disability management is conceived as a proactive strategy oriented to identify and

remove all the factors that prevent people, with any type of disability, from accessing to developing a professional path (Bruyère and Filiberto 2013; Rahim et al. 2017). This conception differs from a more restrictive one according to which disability management coincides with the return to work, of disable people who are already working.

Definition of Disaster Management

A common definition of disaster management is difficult because the term disaster may refer to different situations, and the approaches to manage these situations can vary in scope and aim. A disaster usually refers to an unpredictable event with relevant negative consequences for people, businesses, and the environment. According to the magnitude of damages generated, disasters are detected from catastrophes. With reference to the speed of occurrence, disasters are classified as emergencies or not. Moreover, different literature streams focus on either industrial disasters, which are produced by companies in their ordinary activity (e.g., blow out of some plants) or natural disasters, which are incidence of natural hazard events (earthquakes, eruptions, floods, or cyclones). Managing a disaster is also a very broad definition, as the art of management can span from forecasting to preventing, planning,

solving disasters, and recovering the situation as it was before the disaster or improving it (disaster recovery).

The Nature of Disasters and Crises

A disaster is usually defined as an event, natural or caused by humans, sudden, or progressive, which so negatively affects an organization or community that people have to respond by taking exceptional measures (Carter 1991). Similar, but with some differences, is the concept of crisis, described as a situation faced by an individual or organization, which they are unable to cope with by the use of routine procedures and in which stress is created by sudden change (Booth 1993).

The interchangeability of crisis and disaster is due to the fact that both definitions refer to a situation that the affected person feels unable to cope with and both situations require extraordinary actions to be overcome. However, the concept of crisis has more a transformational connotation as it indicates a turning point that may lead to either positive or negative outcomes. While disasters are always linked to severe negative consequences, a crisis can have a potential negative outcome as well as a positive outcome like being a stimulus for innovation or making the person aware of new targets to achieve. In addition, management research has usually adopted the word crisis to refer to a situation caused by the organization itself, while disaster is used to describe a situation whose root is external, out of organization's control (Faulkner 2001).

This means that disasters are caused by external triggering events or natural events such as extreme weather conditions, and the organization or person is confronted with unpredictable catastrophic changes over which it has little control. On the contrary, crises are attributable to the organization itself because of inept management structures and practices, failure in functioning, inability to adapt to change and therefore to achieve organizational objectives and survival.

This distinction implies that disaster management is mainly recovery or being prepared to deal with the negative impacts caused by an

unpredictable event. Eventually, managers may grasp early warnings about the possible disaster. Instead, crisis management involves the definition of procedures and standards that tend to keep the organization along the desired track. If a crisis is due to internal problems or breakdowns, then managers may set all necessary systems to avoid crisis.

According to this early definition of crisis and disasters, researchers have somehow confused crisis management with risk management as demonstrated by the definition of crisis management provided by Fink (1986) as "the art of removing much of the risk and uncertainty to allow you to achieve more control over your destiny." Since then, the study of crisis management has largely evolved and different models, and frameworks for strategically managing crisis and disaster have been developed (Bundy et al. 2017).

Disaster Management

Disaster management is for today's organizations a necessary capability. Being able to manage a crisis or a disaster is required for survival because globalization has led all organizations to a greater exposure to political, economic, social, and technological changes and their possible negative consequences. The increase in population has generated urbanization and social problems that may hamper businesses and communities. Search for efficiency and productivity has generated excessive use of natural resources and environmental pollution, which are roots of natural disasters, and the greater use and dependence on technology that can break down have increased possibilities of risks, crises, and even disasters (Lee and Harrold 1999). In other terms, crisis and disaster management are important competencies for managers in both the private and public sector. As stated by Kash and Darling (1998), it is no longer a case of "if" an organization, it is rather a question of "when," "what type," and "how prepared" the organization is to deal with crises and disasters. This implies the need for managers to move from a current dominant reactive paradigm to a proactive and holistic approach, which can help dealing with chaos and change.

Disaster management should be conceived as a system of interconnected activities aimed at dealing with a disruptive and unexpected event that may seriously harm the organization. These activities vary depending on the specific situation/event, which can be classified in terms of time pressure (actions are needed immediately or not), extent of control (capability of the company to reduce the impacts with its actions), and magnitude of the incident (the intensity and scope of people involved can be high or low).

If a disaster is sudden and there are no previous warning, organizations are unable to prepare a plan before it arrives, and the range of possible responses is limited. Other disasters are preceded by signals and are slower; therefore, organizations may notice their emergence and even implement management responses as part of the normal management function.

The main stages in managing a disaster are (Ritchie 2004):

1. **Prevention and planning:** In this phase organizations can activate environmental scanning, using scenario planning to forecast risks and understand how risks can become disasters. The most important activity is developing action plans from scanning and defines emergency planning.
2. **Implementation:** This is the decision-making phase, when organizations evaluate alternatives of actions and select the most appropriate response strategy, decision speed is fundamental, and organizations need to have a responsive structure because people and financial resources shall be redeployed quickly to control or minimize the impact of the disaster. During this phase, it is fundamental to define a communication strategy (the company shall try to control messages and information over the disaster using media, appointing a spokesperson, or using public relations plans) and a collaborative strategy with stakeholders, because to resolve the crisis or disaster, it is necessary to have the collaboration of all stakeholders, both internal (e.g., employees and managers) and external (e.g., government agencies, media, general public).
3. **Evaluation and feedback:** This is the phase of resolution and restoration of normality when possible. A key aspect of this phase is the analysis and evaluation of organization's effectiveness in solving or softening the negative impacts of the disaster. Companies shall learn from the disaster and use feedback to improve planning. The disaster can be the turning point for a change in company's strategies or internal functioning.

These three phases of disaster management are linked to the life cycle stages of crises. Both crises and disasters actually go through series of progressive stages whose knowledge may help managers to decide which actions to take to stop crises moving into the next stage. According to the management literature, we can identify four stages in the life of a crisis or disaster:

- **Pre-event:** when the disaster has not yet occurred, therefore, actions can be taken to prevent it or mitigate the effects of potential disasters.
- **Emergency:** the stage when the disaster has hit the company or population and managers shall implement strategies of damage limitation.
- **Intermediate phase:** when people's short-term needs shall be satisfied (e.g., providing a house) and the main objective is to restore the community or the organization to normality as quickly as possible.
- **Long-term phase:** the phase of continuing recovery, continuous support of the affected people (e.g., counseling victims, repair of damaged infrastructure) and provision of suggestions, and feedbacks to improve prevention and revise disaster management strategies.

When focusing on disasters caused by businesses whose impact is limited to a narrow territory or scope of operations, managerial actions can be organized and conveyed to solve the situation. In case of large disasters that involve a huge amount of people like political crisis or huge natural disasters, it is much more difficult to identify the stages of the disaster and the proper actions to take. When several factors are involved, an intermediate phase can turn back to be an emergency because additional issues arise or the implementation phase can last forever because

coordination at the political or regional level is complicated, and communications, which lack of direction, increase confusion and inability to minimize damages.

Disciplines Involved

Disaster management does not only refer to businesses. Practices of managing natural disasters originated long time ago. Even the story of Noah's ark to save human kind and animals is a management strategy to cope with a disaster. Modern disaster management as set of strategies, standards, and coordinated efforts to address preparedness, mitigation, and response activities to harmful situations dates back to the mid-twentieth century when governments began to create systems aiming to protect citizens from wars.

Business researchers began to deal with this topic in the 1980s when first large-scale industrial disasters became public. Therefore, business literature should be integrated with knowledge developed in other fields of research and disciplines such as:

- Public relations and communication (because the use of communication to control crises and disasters is fundamental as well as to improve coordination between internal and external stakeholders)
- Geography and environmental management that may help in understanding natural hazards disaster management
- Leadership styles (because implementation and (in)effective crisis management is strictly related to the leadership function)
- Political science (because terrorism, political instability, and security crisis have pushed governments to develop disaster management strategies already long time ago)

Interconnections with such disciplines has led to the development and adoption among businesses of specific tools that help to react to early warnings of a disaster arriving. For example, contingency planning and emergency planning are strategies developed within the field of public civil protection that can also help businesses to

stop a crisis/disaster from occurring or to limit its impacts on business and society.

Contingency planning refers to the identification of alternative plans, which can be implemented if a disaster hits, for example, when an airplane crashes or a plant blows up. In this case, the plan can include finding free accommodations for all people involved or moving employees from one site to another one. These plans are helpful for less certain situations and can help resolve the situation quickly if they were to occur. Integrated emergency planning (mainly used in natural disasters) includes planning of advance warning systems, creation of a disaster management command center, and prepared coordination between emergency services and public authorities.

Summary

Despite the fact that there is a difference between the words risk, crisis, and disaster, these are closely interconnected and often used interchangeably. Within the field of businesses, it is important and almost a necessity in today's era to set a risk management strategy and a system for managing crises because if these risks are neglected and crises mismanaged, they may lead to disaster.

systemizing, defending, and recommending concepts of morally right and wrong conduct. It may be divided into four major areas of study, namely

- Meta-ethics
- Normative ethics
- Applied ethics
- Descriptive ethics.

In the context of sustainability management, usually, normative and applied ethics play a major role – the first one by trying to define values, norms, and rules that enable individuals as well as groups to live a good, decent, and peaceful life; the latter by applying these normative orientations to specific areas of decision and activity, such as medicine, engineering, digitization, economics, business, and management (see, e.g., Pieper 2003; Ricken 2003).

Descriptive ethics deals with the different answers that humanity represented by different religions, cultures, and institutions has found throughout time and history for the question of “how should we behave and treat each other” (One of the most famous projects of descriptive ethics in the late twentieth century is the so-called Project World ethos by Hans Küng (1990)). Meta-ethics is analyzing and systemizing overarching principles and formulas that allow for the definition of normative orientations with a legitimate claim of universal acceptance and validity (see, e.g., Spaemann 1986; Pieper 2003).

This part of practical philosophy also compares the different (scientific) approaches of normative ethics and develops categories for differentiating them. One of these categorizations is dividing ethics into teleological (derived from the Greek term “telos” = goal) and deontological (derived from the Greek term “deontos” = duty) approaches (see, e.g., Frankena 1973, p. 14).

From the perspective of teleological ethics, an action is morally justified, thus ethically correct, when it serves the achievement of an overall goal that is recognized as a highest value and/or last end of humanity (e.g., happiness, eternal life, justice, social welfare, and sustainable development). The legitimacy of an action is considered and justified with regard to the expected outcome (ex post). Internationally, Utilitarianism –

Discourse Ethics

Annette Kleinfeld¹ and Annika Martens²

¹Department of Economic, Cultural, and Legal Studies, University of Applied Sciences – HTWG Konstanz, Konstanz, Germany

²Hochschule Fresenius – Department of Economics & Media, University of Applied Sciences, Hamburg, Germany

Introduction: The Context of Discourse Ethics

Ethics, also known as moral or practical philosophy, is a scientific discipline dealing with

developed since the early nineteenth century by Jeremy Bentham (1784–1832) and John Stuart Mill (1806–1873) – is probably the best-known example for this category as it has become the normative foundation of modern, especially, neo-liberal economic and market theory. According to Bentham, the overarching scale of human action is benefit – if possible both of the individual and of the (largest) group (Bentham 2013, chapter I–II). In the economic and corporate (managerial economics) context, “benefit” has been translated by “wealth,” “growth,” respectively, by “profit” and “economic success” (see Kleinfeld 1998, p. 33).

A general critique of this category of ethical reasoning argues that it could be interpreted in a way that “the end justifies the means,” neglecting, thus, the evaluation of the ways to achieve the respective goal from an ethical viewpoint as well.

From the perspective of deontological approaches, in contrast, only decisions and activities which are following moral orientations with a legitimate claim of universal validity (e.g., the principle of reciprocity/mutuality, rationality, respect of human dignity, and freedom) are morally justified. The legitimacy of an action, thus, requires a check beforehand (a priori) whether the underlying motives, attitudes, or the guiding principles or “maxims” fulfill this requirement. The most famous example for this category is the practical philosophy of the German philosopher, Immanuel Kant (1724–1804), the principle used to check the universal validity is his Categorical Imperative:

Act only according to that maxim whereby you can, at the same time, will that it should become a universal law. (Kant 1911, p. 420)

One major critique of the Kantian ethics came up in the twentieth century against the background of two world wars as well as new societal and technological challenges like nuclear power, arguing that an ethical theory which is primarily referring to individual decision-making is not appropriate any more. German philosophers and sociologists, like Max Weber (1864–1920), criticized its mere focus on the individual motivation and inner attitude of the actor, neglecting the (long-term) consequences of activities that had

been qualified as morally legitimate. In his famous speech “Politik als Beruf,” held in 1919, at the University of Munich, Weber was contrasting this “ethics of conviction” with the need for an “ethics of responsibility” (Weber 1988, pp. 551–552), which was taken up by Hans Jonas later on: With his ethical approach developed in “Das Prinzip Verantwortung” (Jonas 1979), he laid the normative foundation of environmental ethics and an ethics of sustainable development including the responsibility toward future generations.

Against this background and historical situation, the German philosophers Karl-Otto Apel (born 1922) and Jürgen Habermas (born 1929) started to develop from the 1970s on a new version of deontological ethics called “discourse ethics.” On the one hand and in common with the Kantian ethics, it belongs to the tradition of cognitivist moral theory. This means that it follows the assumption that justifying the validity of moral norms can be done in a manner analogous to the justification of facts based on rational insight of human beings. The free will of Kantian ethics corresponds in discourse ethics to the free will of the individual to participate in an open and rational dialog. On the other hand, discourse ethics continues the tradition of theories acknowledging the importance of language and communication for reflection in general, for moral arguing in particular that had started with Aristotle’s “Rhetoric” and had been rediscovered in the nineteenth and twentieth century by philosophers like Hamann, Herder, and von Humboldt, respectively, Wittgenstein, and the Erlangen School of constructivist theory (for the historical context of discourse ethics. See, e.g., Böhler and Gronke 2011).

Mission, Objectives, and Principles of Discourse Ethics

One essential idea of discourse ethics is to determine ethical norms of behavior not only on the individual level but also by including the perspectives and rational arguments of those who would be potentially affected by the decisions and activities following these normative orientations

(Habermas 1983b, pp. 53–125). Unlike Kant, Apel and Habermas were convinced that the validity of a moral norm cannot be justified in the mind of an isolated individual reflecting on the world but only intersubjectively in processes of argumentation between individuals following a certain set of rules. The validity of a claim to normative rightness depends upon the mutual understanding achieved by individuals in argument (Habermas 1983a, p. 60; see also Kleinfeld 1998, p. 30).

Like Kant's Categorical Imperative, discourse ethics is a formal ethics, i.e., it only describes and prescribes the procedure needed to define moral orientations legitimately claiming universal validity, whereas the content, the object of the examination by this procedure, have to be raised in terms of hypothetical moral norms by the members of the society respectively by the members of the discourse community. The concrete determination of moral norms as legitimate or not takes place in a dialog which has to follow certain rules (Habermas) and requires certain preconditions called "presuppositions" by Apel. The actual criterion of normative validity of an orientation consists in the **consensus** that the persons involved in a discourse of this kind and quality achieve (Habermas 1983a, pp. 97–100).

The rules for such a discourse set up by Habermas are ranging from morally neutral, logical ones – like, e.g., that terms have to be used in the same meaning or that speakers are not allowed to contradict themselves – via dialectical ones with an ethical content – e.g., every speaker may only claim what he or she believes him/herself – to rhetorical rules like every individual who is able to speak and act may participate in a discourse and should not be hindered to do so by any internally or externally generated force (Habermas 1983a, pp. 97–100). They are prescribing an ideal situation of communication which according to Habermas and Apel are necessary preconditions for a true discourse.

Whereas Kant extracted moral principles from the necessities forced upon a rational subject reflecting on the world, Apel and Habermas, thus, extract moral principles from the necessities forced upon individuals engaged in the discursive

justification of validity claims. In the perspective of Apel, these are the kinds of idealization that individuals have to make in order to enable communication and argumentation at all, for instance, the mutual respect and the mutual acknowledgment of the ability of rational arguing of individuals involved in any kind of communicative activities.

In Habermas' version of discourse ethics, two principles are essential which have a similar status as the Categorical Imperative for the Kantian ethics:

1. The **principle of discourse "D"** stating that norms are valid only under the circumstance that they find (or may find) the agreement (Zustimmung) of all affected persons as participants of a practical discourse (Habermas 1983b, p. 103).
2. The **principle of universality "U"** which states that valid norms at the same time have to fulfill the precondition that in case of a general application of this norm the consequences and unintended effects which are (most probably) resulting for the interests of each individual can be accepted by all affected persons (and will be preferred to the consequences of any other (existing) rule or normative orientation) (Habermas 1983b, p. 75).
3. Universal validity, thus, will be fully achieved only if the perspectives of all, directly or indirectly by the norm affected, persons have been integrated into its determination and if these persons may agree to it (Habermas 1991, p. 59).

Apel is taking up the two principles from Habermas but formulates them much stronger in the form of an imperative maxim of action, thus getting closer to the Categorical Imperative of Kant:

Act only out of a maxim of which you, based on a real agreement with the affected persons (or their legitimate representatives) or – substitutional wise – based on a thought experiment, may assume that the consequences and unintended effects that most probably will result from its general application for the fulfillment of the interests of each individual could be accepted (unforcedly) in a real discourse by all affected persons/ parties. (Apel 1988, p. 123 (translated into English by the authors))

Besides, in addition to Habermas, Apel is demanding to carry out a practical discourse even if the conditions of an ideal discourse are not given yet. Even though the creation of these ideal conditions, mainly the assurance of a voluntary situation of dialog free from any kind of suppression and based only on the power of the stronger argument, remains an important goal for him too, there may be situations where getting into a practical discourse based on the ordinary rationale of a “strategic self-defense” has to be considered as the second best option and, as long as the presuppositions for an ideal discourse community do not exist, seen as a “duty of secondary status” (Apel 1988, p. 128).

Reception, Application, and Relevance of Discourse Ethics in the Context of Business Ethics and CSR

In principle, all kinds of applied ethics (see above) could become a field of application of the ideas and principles of discourse ethics, both of its ideal and of its practical version. The latter, for instance, could be realized by engaging experts and potentially affected parties in a (practical) discourse in order to find a consensus about controversial questions such as the legalization of drugs, the permission of abortion or of assisted suicide, or – more recently – about the need of a normative framework for the ethical implications of digitization and artificial intelligence.

One area of applied ethics which was using the theory of discourse respectively of dialog ethics explicitly as a foundation for some of its approaches was the discipline of business ethics in the German-speaking area of Europe, in the first place, the theory of Peter Ulrich, holder of the first chair of business ethics at the University of St. Gallen. In his books “Transformation der Ökonomischen Vernunft” (1987) and “Integrative Wirtschaftsethik” (1997), Ulrich demands a transformation of economic rationality by reconstructing its implicit utilitarianist ethical fundament with the categories of communicative ethics in the sense of Apel and Habermas to what

he calls a “rational social economy” (Ulrich 1987, pp. 269–304; see also Kleinfeld 1998, pp. 33–34).

Ulrich is restricting the use of this approach to the ideal discourse in the form of the “regulative idea of finding a consensus based on rational arguing” (Habermas 1983b, p. 55). This idea should be applied by economic theory itself in order to critically reflect and question its own underlying normative assumptions with the aim to (re)define economic rationality and the genuine purpose of economic activity. “Rational” in terms of Ulrich’s understanding are only those economic activities or institutions that “free and responsible citizens within a process of rational communication and understanding among all affected parties would define (respectively could have defined) as value creating” (Ulrich 1990, p. 133 (translated into English by the authors)).

Another example of applied discourse ethics – here in the sense and dimension of a practical discourse according to Apel – can be seen in one of the most important elements of a contemporary approach of CSR management, namely, in carrying out a dialog with at least the most important stakeholders of an organization. In order to understand and define stakeholder dialog as a form of a practical discourse in line with the above described, one major criterion that has to be considered in the identification of relevant stakeholders is their affectedness by the corporate decisions and activities, following the definition of stakeholder, e.g., of Edward Freeman (Freeman 1984, p. 25) as well as of the first international standard in the area of Social Responsibility Management: ISO 26000 (ISO 26000 2010, pp. 4 and 17).

While in clause 5 (ISO 26000 2010, pp. 17–18), the standard provides clear guidance about a proper identification and involvement process of relevant stakeholders in-line with the principle of ethical behavior and the other six principles of social responsibility defined in clause 4 (ISO 26000 2010, pp. 10–13), the development process of ISO 26000 itself can serve as an example for applying the ideas and the principles of discourse ethics in the form of a practical discourse.

The standard has been developed between 2004 and 2010 based on a huge global multi-stakeholder process, facilitated by the International Standard Organization ISO and, thus, following the specific rules of standardization set up by ISO: All ISO standards with the legitimate claim of being recognized as an international “norm” are developed in line with a certain set of rules. Next to the inclusion of as much countries as possible as well as of all stakeholder groups relevant for the respective topic, the most important ISO rule is to develop the content of the standard based on the principle of consensus. This means that the facilitators of the process try to create an agreement of all involved persons and parties, in particular, about the underlying terms and definitions. In the case of ISO 26000, the development process became the largest in the history of ISO, including the representatives of 99 countries and 6 stakeholder groups per country. In addition, the so-called D-Liaison-Organizations were invited, who were known to have a long-term expertise in the fields relevant for the different aspects of social responsibility such as ILO, UN Global Compact, The WHO, the European Business Ethics Network – EBEN, experts from the European Commission, etc. (ISO 26000 2010, p. V; Kleinfeld 2011).

The inclusive nature and procedural fairness of its development process, described above, its consensual orientation, and its transparency lead the outcome of this standard to possess a high level of legitimacy as a number of authors in the area of business ethics and CSR have acknowledged after its publication (see, for instance, Mueckenberger and Jastram 2010; Mena and Palazzo 2012).

Introduction

Innovation consists a continuous challenge for every corporation which has the ambition to make the difference inside its market by obtaining a competitive advantage. Innovation is tied closely with technological leapfrogs. However, innovation is not exclusively about technology. The concept of innovation could be about a new technological achievement, a new idea, a new process, a new product or service, or a different way of thinking or usage of something. The continuous chase of dominance in market by corporations and humans' trend for continuous success has led companies to be unsatisfied by making just an innovation. They are interested in the rationalization of innovation, the successful repeat of innovation process, the practical employment and materialization of any innovation in their market, and the yielding of any possible benefit. Especially, disruptive innovation, a term that was introduced in 1995 (Christensen & Bower, 1995), seems to be a goal for more and more companies which wish to agitate the current status quo in their sector by bringing different products and services than competition even with less resources.

Definition

Disruptive innovation consists a process in which new entrants challenge incumbent firms, often despite inferior resources and offerings. This may occur through two alternatives. New-comers or small size firms may select overlooked segments of the market with a product considered inferior by incumbents' most demanding customers and later move up-market as their product is upgraded. Or they may form markets where no market exists and turn nonconsumers into consumers. Basic element in both scenarios is the caused disruption in the market. This kind of innovation is not about technology alone but rather the combination of technology and business model innovation (Hopp et al., 2018).

Disruptive innovation is a process and not just an amazing product or service, with specific starting and ending point that brings an offering by a small company from fringe to the mainstream (Christensen et al., 2015: 6).

Description

The word “disruption” delineates a process whereby a small company with limited resources achieves to challenge the major companies in the sector. As the incumbents have stabilized their dominance in the market and design new ways to increase their profitability by upgrading their products and services for their most important, demanding, and profitable clients they unintentionally show defiance of the needs of some low-end segments of the market by exceeding their needs and their buying capacity with their new products. This is the entering point for small players and/or newcomers to detect and target these overlooked segments and finally provide more proper products and services in more competitive pricing than dominant players. The reality that big players have shifted their interest to other segments has as consequence that they ignore and underestimate the intrusion in the market and are characterized by inertia instead of reacting promptly. Small companies continue their growth by expanding their targeted groups including even the main customers of the incumbents. Thus, small players scale up to the market by improving their quality continuously, but they always maintain the characteristics that have allowed them to enter the game so dynamically (Christensen et al., 2015).

Disruptive innovations don't catch on with mainstream customers until quality catches up to their standards (Christensen et al., 2015: 5).

A disruptive innovation concerns a detailed designed prototype product, service, or business model that unfolded gradually approaching more and more segments of the market, starting from a low-end niche and targets to mainstream customers. This initiative sources from a small company that manages to disrupt the main players of the market by placing a new, low-cost offering. The initial niche market acceptance yields profit

that funds further development of the offering or business model to upgrade its quality and capabilities. Afterward, it can earn new customers from other niche markets with higher standards. Mainstream customers gradually become aware of the innovation, and they start considering it as a potential purchase. When this purchase occurs in the level of mainstream customers, the disruption has occurred (Thomond & Lettice, 2002: 4).

Sometimes, the disruptive innovation evolves the birth of a new segment in the market that did not exist previously usually because of high-cost reasons. As a consequence, in the case of new-market footholds, the disruptive innovation implies that the small player manage to bring new customers in the game (Christensen et al., 2015: 5).

Sustaining Versus Disruptive

The term sustaining innovation is discrete than disruptive innovation because the first refers to cases where we have incremental improvements in existed products and services usually by companies that have big shares in the market. Disruptive innovation concerns revolutionary rather than evolutionary changes regarding technology, products, services, or business models. Incremental and evolutionary innovation consist improvement of already established offerings based on mainstream customers' expectations by major companies that control the biggest shares of the market. Evolutionary innovation assist big players to maintain and increase their customers (Christensen, 2013). Mainstream dominant companies pay much attention to their existing customers and especially to those that offer higher profit margins. Big players have a strong desire to fulfill the expectations of their high-end customers without any risk for their profitability. They are directed to any solution that is familiar, mature, and proximate; thus, they unintentionally put away themselves from any disruptive path that may hide risk and uncertainty. Furthermore, everyday business routine puts ordinary issues ahead of incumbents and they get used not to use disruptive thinking (Thomond & Lettice, 2002). Thus, this

adhesion of well-established companies to further develop their already high-end offerings put them away for the path of disruption. So, company's resources are directed more to sustaining innovation rather than disruptive innovation, since the first kind will most probably create more profit for the company (Christensen et al., 2015: 10–11).

Christensen (2013) describes as value network the frame within a company interacts with its customers, realizes their needs, expectations, issues, difficulties, receives feedback and acts based on that, competes with other companies, and chases profit. In incumbent companies, the consideration of major changes implies high risk, and thus the allocation of resources is directed toward sustaining rather than disruptive innovation. Trott (2001) claims that typical market research cannot push a firm to disruptive direction and possibly it can encircle a firm inside incremental innovation context (Trott, 2001).

The graph below presents the parallel paths of sustaining and disruptive innovation. Sustaining innovations brings a better version of an existed product. On the contrary, a disruptive innovation implies an offering with some prototype characteristics that initially is substandard in the eyes of

incumbent's customers because of its low pricing. They will reconsider their opinion up to the point that the quality will rise significantly as the small player moves upmarket. They find such offerings appealing when their quality satisfies their standards, and the competitive pricing makes them to proceed with purchase. At the point that small players have managed to earn clients from the major segments of the big companies, they have completed a disruption (Christensen et al., 2015: 4). Main characteristic of disruptive innovation is that it evolves low-end companies or new entrants that plan to satisfy the less demanding customers of the dominant companies with a "good enough" product in a cheaper price. This is how disruptive innovation works: The small companies move upmarket gradually and total pricing of the market moves down. Thus, disruption is in favor of the customers since the new offerings are tailored just to satisfy their needs and they are easier to be purchased than before (Christensen et al., 2015: 6). The challenge for every modern company is to establish a corporate culture and an R&D mechanism that will allow it to continually produce disruptive innovation as a stable response to market competition (Thomond & Lettice, 2002: 4).

Disruptive Innovation, Fig. 1 Sustaining Vs Disruptive Innovation (Christensen et al., 2015)

Disruptive Innovation in Depth

Disrupters are mainly interested in the design and application of the proper business model rather in the perfection of the first versions of their offerings. (Christensen et al., 2015: 6)

There are three kinds of disruptive innovation. The first consists of cases where low-end companies find a foothold with a good-enough new product and/or that satisfies low-end customers in pricing and quality. The second consists of cases where newcomers enter a wide market with a totally brand-new product and/or that is not initially competitive to the existed high-end products of the incumbents. In the third case, there is a newcomer that introduces a brand-new product to the world offering (business model, product, service, or combination of them) targeting exactly below the low-end zone of the customers of the market. In the first case, the big players overlook the smaller companies up to the point that low-end companies decide to move upmarket. In the second and third case, big players may not consider the totally brand-new product as a threat since they cannot understand its dynamic (Christensen et al., 2015: 10).

There are researchers that disagree with the use of the term “disruptive innovation” for any innovation like technological innovation, product innovation, service innovation, and business model innovation because they consider that these types even could cause disruption to incumbent companies; they have significant differences. These innovation types create different results having different main characteristics, and thus a generalization of them is not fruitful for better understanding. Christensen in 1997 had initially focused on disruptive technologies and later extended his theory by embracing products and business models (Markides, 2006).

Business model innovation consists in bringing a prototype business model in an already established market. The example of Amazon represents this term since it has contributed to the book retail business by using a discrete and new way of operating. EasyJet is another example of a successful business-model innovation (Markides, 2006).

Such a disruptive business model innovation should maximize the market either by attracting new customers or by increasing the consumption of the existed customers. Amazon and easyJet have managed to introduce an unusual business model and have expanded their markets. Both did not create a new product or service or even technology. They have managed to repurpose what an already existing product or service could be and could be offered to the public. Amazon, for example, achieved in its early steps to reform the book-selling service. A prototype business model reintroduces an ordinary product or service giving special characteristics to it. Thus, these disruptive innovators do usual business with an unusual way that implies much lower cost for them and their customers and disrupts the market. Since newcomers highlight different attributes of an offering, customer groups different from mainstream customers are interested in this offering, usually customers from the low-end level and/or totally new customers (Markides, 2006).

Disruptive innovation that is based on a new-to-the-world product disrupts consumers, producers, and retailers. It is very common in newly formed markets, a big number of start-ups to emerge with new products based on radical technology. This impressive increase in new entrants' number occurs well before a new market extends. The pace of innovation at the beginning of a new market is the highest achieved during its life cycle. Such a new market will start taking stable characteristics when most of these pioneers will be disappeared because finally a specific design will prevail. The early pioneers are not necessarily the companies that will become the incumbents in the new market. It seems that firms that enter in a niche before the prevalence of a specific technological solution have the chance to ride the wave of innovation and enjoy the benefits for their commercial application better than early pioneers. These companies do not outperform in the field of radical innovation but in the commercial field because they achieve to transform a niche to a big market, they build a brand, invest in marketing and distribution channels, and proceed with mass production and economies of scale (Markides, 2006).

A purely disruptive innovation that has all the characteristics of the theory of disruptive innovation is not going to be successful inevitably. Moreover, it is possible an effort by a small player that causes disruption in the market to be successful even if he has not followed all the theoretically correct steps of the disruption process (Christensen et al., 2015).

There is a common element between the case of disruptive innovation based on a new product where the latecomers take advantage from early pioneers and the case of disruptive innovation based on a new business model where small players disrupt the incumbents. Both take advantage with a product that is not the best quality wise. Latecomers manage to shift the decision-making from technical characteristics to others like pricing, quality, and branding and focus on a mass market segment. Disruptors like small players and new entrants with a new business model achieve to shift the decision-making process away from technical characteristics and branding to pricing and probably to redefine the content of their offering in comparison with the incumbents. It is pitying that early pioneers who have managed to develop technology and invent new products lose the advantage and the foothold in the market they have created, by the latecomers. Proportionally, early pioneers and incumbents react in a similar way. Both continue to invest in the incremental improvement of their products. Early pioneers have a product that covers the needs of the average user, and they continue to invest in its overengineering. Finally, they create a product that is more than good enough for the average user, and it is of high cost. The latecomers and small players notice that discrepancy, and they try to reach those who cannot afford to pay for a very expensive product which does more than what an average customer needs. Early adopters are interested in any new improvement, but the average customers prefer a balanced product with good technical characteristics and good pricing. Of course, there is a big difference between the two examples. In the case of disruptive product innovation, the latecomers dominate the game, but in the contrary, the small players with a prototype business model do not necessarily take the place of the incumbents. They probably earn an important share in the market which big players can afford to lose (Charitou & Markides, 2003).

Reaction to Disruptive Innovation

Disruptors often follow different business models than those of the incumbents and their success is based more on the functionality of their unusual business model rather in the superiority of their product or service (Christensen et al., 2015: 7).

The fact that the small size companies or newcomers respond either to low-end segment of the market or in a totally new niche indicates that there are fundamental differences from the mainstream and the high-end customers. Thus, the idea of a dominant company to imitate a small innovative company is extremely difficult and even risky because the biggest part of their customers has different expectations than the customers of the innovator. Furthermore, such transformation requires a different value chain, and all the aforementioned information may explain the reason behind the delay and reluctance of a big player to respond to such disruptive innovation challenge. Gradually, the innovative shift upward in the market and its proposal to the market start to compete with the major solutions proposed by the big players. At this point of time, as customers of the mainstream level get added in its customers' base, incumbents cannot overlook the phenomenon. However, it is difficult for an incumbent to respond with a nonsustaining innovation (Disrupt the Disruptor Strategy) since the introduction of a new business model is a vast transformation that demands time and has great risk. Christensen & Raynor (2013) suggest that at this certain point of development, the big players must react by creating a separate unit that will imitate the newcomers or they must buy the newcomer unless they wish to disappear themselves from the market. The resources from the mother company could assist the new unit to succeed quickly. On the contrary, Markides (2006) suggests that there is another strong alternative that is dictated by real business life. The innovator gets bigger and after a rapid growth reaches a limit that is an important but not a dramatic share of the pie of that market from the point of view of the incumbents. The dominant companies do not collapse, and they can continue as protagonists in their sector. The prototype business model is not necessarily better than the

traditional model; it may become dominant in the market, or it could take a respected percentage of a market. Therefore, a response by the incumbents like a parallel creation of a new unit, the full adoption of a new business model, the acquisition of the newcomer, the “disrupt the disruptor” strategy, and the closed follow-up without any special reaction remain as available options (Markides, 2018).

However, incumbents could consider the possibility to use a disruptive business model when: (a) They prepare their entrance in a new market, (b) they are in the middle of a crisis because their existed business model is superseded and they need a push, and (c) they are about to introduce a prototype product and they target to their mainstream customers (Markides, 2006).

A disruptive innovation when it comes from a well-established company, either this is a response to a first disruption in the market by a smaller company or it is not, usually demands a radical change in its value network. Real data indicate that incumbents can better tackle newcomers and outliers through sustaining innovation since they have the channels of communication, more resources for R & D, etc. Small size firms maintain better possibilities inside a disruptive innovation complex. However, this is not absolute. In any case, the dominant companies should neither ignore nor overreact to disruption invasions by abandoning parts of their core customers in the high end of the market. They should better follow up closely the disruption and seek for any new chances for growth (Christensen et al., 2015).

Disruptive strategic innovations are not necessarily superior to the traditional ways of competing, nor are they always destined to conquer the market. Rushing to embrace them can be detrimental for established companies when other responses, including ignoring the innovation, make more sense (Charitou & Markides, 2003: 2).

Summary

Disruptive innovation engages the concept of disruption in an already established market either by the rise of a small already existed firm or a newcomer that will bring a new prototype idea launching from the low-demanding customer

zone or in a new low-cost market. Disruptive innovators follow a process where they introduce a proper offering usually inferior in quality and with inferior resources. They often employ a combination of a new technology and a prototype business model. Disruption represents innovations that make products and services more accessible, affordable, and available to a larger population. They focus on customers' needs, and they transform a gap in the market into a chance for them to grow. Even if they manage to grow up and compete the incumbents, they may overtake them or coexist with them in the same wide market. The other side is consisted of the incumbents that have several options to examine and apply due to their higher capital power. However, their inherent features determine their choices as the same applies for newcomers and/or small companies.

For disruptive innovation, the key to organizational renewal may lie in the needs of the customers and/or the dynamic of a critical mass of noncustomers which could be transformed into new low-cost customers creating a new niche market (Hopp et al., 2018). Furthermore, the change of the general framework of the market or of the society in general with revolutions, wars, radical scientific achievement, etc. or just the finding of a clever way for economies of scale may indicate the path for some cases of disruptive innovation even though there were no pioneering companies that step forward unexplored territories but rather clever businessmen looking for chances (King, 2015).

In any case, the business reality is not defined by the already developed theory rather it finds always a new prototype and innovative ways to surprise everyone. Making predictions in business cases where there are incumbents that are challenged by disruptive innovation threats is of high risk.

Disruptive Sustainability

Ioannis Φ. Panagiotopoulos
Independent Researcher, University of the
Aegean, Chios, Greece

Synonyms

Corporate social responsibility; Disruptive innovation; Sustainability

Introduction

Requirements toward sustainability are diffused in all aspects of business sector with continuously higher pace. This implies the corporate need for alternative solutions that could reduce environmental footprint and increase social profile. This corporate trend for sustainable transition could be transformed into a chance for companies to increase their corporate social performance (CSP) through innovation. Disruptive innovation in a wide context could consist a double way to foster changes toward sustainability and enhance corporate financial performance (CFP). As the demand for an absolute turn to sustainable solutions is maximizing, disruptive innovations for the sake of sustainability will be an ultimate challenge. These changes in markets, regulations, institutions, practices, technologies, etc. imply new niche markets and differentiation to value networks and finally a kind of disruption in the existed system. New ideas like Internet of Things (IOT), new healthcare and transportation solutions, smart cities, intelligent energy services and smart grids, and circular and sharing economy models could operate as lighthouses for a total transition to a new sustainable reality worldwide (Nasiri, Tura, & Ojanen, 2017).

Theoretical Background

Major changes are characterized as fit-and-conform when they are mild or stretch-and-transform when they are more radical and deeper. The urgency of the global problems, like climate change and environmental degradation of the planet, applies significant pressure for scientific innovations that could reduce human impact in nature. However, these changes cannot concern only science or technological products since business players should also change their spherical view of things. There is a general claim for sustainable transition directed to corporations, and disruptive innovation could operate as the proper vehicle for that. Technological and social innovations could function as enablers for disruptive sustainability transitions (Kivimaa, Laakso,

Lonkila, & Kaljonen, 2021). Geels and Schot (2007) describe disruption as an incremental and rare change of high impact in an incumbent system. They consider disruptive change as the cultivation of the proper conditions that could favor a transformation or a technological substitution process. On the contrary, the term “reconfiguration” refers to innovations that are employed to facilitate local issues and cause small improvements in the status of the market.

We should underline that the term “disruptive innovation” is not identical with the term “disruptive sustainability.” Disruptive innovation describes a prototype offering usually with inferior characteristics than competition, that is introduced by a small company, achieves to make a serious impact in the existed market and the incumbent companies. The main characteristic of disruptive innovation is that it involves low-end companies or new entrants that plan to satisfy the less demanding customers of the dominant companies with a “good enough” product at a cheaper price (Christensen, Raynor, & McDonald, 2015). Furthermore, “sustaining innovation” refers to incremental improvements in existed offerings in order to satisfy the most demanding customers and increase market share (Christensen, 2013). Therefore, there is a proportion between the dipoles of disruptive innovation and disruptive sustainability, on the one hand, and sustaining innovation and reconfiguration, on the other. Disruptive innovation toward sustainability is not used herein with the stringent abovementioned meaning that Professor Christensen has defined but within a much wider frame. This means that any prototype idea, either in the level of technology, business model, practice, product, or service that could disrupt the regime and destabilize the existed socio-technical-economic system by introducing something new that signals a transition to a more sustainable phase of a market, could be characterized as disruptive sustainability.

Definition Disruptive sustainability is about disruption related to sustainability transition where there is a significant change in the architecture of a socio-technical-economic system. This change should be of high-intensity impact and long term

pertaining one or more parameters of the system like incumbent technology and companies, infrastructure, markets, business models, regulations, strategies, practices, actors, value networks, behavior, and cultural models (Johnstone et al., 2020; Kivimaa et al., 2021).

Disruptive Sustainability Versus Disruptive Innovation

Sustainability transitions demand new knowledge, resources, and skills. A disruptive sustainable innovation implies a destabilization of the regime in case of a stretch-and-transform transition. On the contrary, in the case of a fit-and-conform transition there is no destabilization. A reconfiguration-based transition process concerns gradual change of the current situation and thus operates in a different way than disruptive innovation (Kivimaa et al., 2021). Thus, the cases of fit-and-conform transition and reconfiguration-based transition are closer to sustaining innovation. The extension of the initial meaning of disruptive technology to disruptive innovation that embraces cases like new business models, prototype products, or services indicates paths through which a disruptive system change could occur. There are two scenarios through which a prototype business model relates to disruptive system change: (a) disruption in business models as an outcome of disruptive technological innovation and (b) prototype business models that disrupt the incumbent system. Disruption limits the current value of existing corporate assets and makes obsolete existing business models of the major players (Lindberg, Markard, & Andersen, 2019). The example of electric vehicles and mobility-as-a-service, including ideas as car sharing, is such disruptive innovation toward a sustainability transition that disrupts the incumbent transport and energy companies with an innovative product and a service-oriented business model and a user-centric approach that breaks the established rules of the market (Kivimaa et al., 2021). As an innovative business model is disruptive itself, it could have great impact in a market affecting the core of its operation like in the case of sharing economy (Kivimaa et al., 2021).

A disruptive innovation does not necessarily imply that the incumbent firms will lose their dominance in the market. There are possible incumbents to share the market with new entrants and innovating small companies. Incumbents have a range of options as reaction to disruption like investment in sustaining innovation, adoption of a different business model, creation of a new business unit, the acquisition of a newcomer, the “disrupt the disruptor strategy,” or even absence of any reaction (Markides, 2018). In the case of disruptive sustainability, it is possible for a market to get enriched with new entrants like in the case of autonomous vehicles where companies from IT and telecommunications fields have entered the transportation sector (Skeete, 2018). However, in this case, it seems impossible that incumbent firms survive without any strategy against disruptors that includes a sustainable shift because sustainability consists a global necessity worldwide. Disruptive sustainability could cause changing of ownership from major players to newcomers, and moreover, a part of ownership could be allocated to customers, civil society, groups of citizens, other companies and government, or more local authorities like municipalities. It is expected that this could be the case in the field of transportation with the coming of renewable energy, electric cars, and autonomous vehicles. Elements like prosumerism and ownership sharing could in combination with the technologies reform the traditional sector of personally owned and manually driven cars. The privately owned mobility will be transformed into a transportation service where shared cars will look more like platforms, the core of the platform will be the software rather than the engine path, and a disruptive sustainability phenomenon will have taken place (Skeete, 2018).

The Transition from Old to New

A process of transition implies changes in practices, behavior, cultural models, ideas, and perceptions; therefore, it could be considered a

disruption. Disruptive sustainability could be distinguished to three categories: (a) disruptive innovation which causes changes in behavior and practices, (b) new developed practices that replace existed practices, and (c) significant changes in cultural models (Geels, 2010). The model of sharing electric cars could in the aftermath cause changes to the maintenance practices and processes. The car-sharing possibility and e-bikes could transform the urban habits of citizens. However, in the case of car-sharing practice, this change has the dynamic in a later stage to decrease the use of means of public transport, and this could be considered against environmental protection; thus, it could not be considered a sustainable transition. The mention in cultural models could pertain to corporate culture or a social culture. A corporate culture that easily accepts changes and focuses on continuous development could more easily produce innovation, adopt changes, and reposition itself closer to sustainability (Kivimaa et al., 2021).

Disruption and destabilization are two terms with similar but not identical content. Disruption is related with the speed or the intensity of the impact on the sociotechnical system. Destabilization is used to describe a phase or process of transition. The aggregation of functionality issues and the pressure from stakeholders of incumbents could define the dynamic of the destabilization. The speed of the transformation could be characterized either as fast or gradual. The intensity of the transformation could be measured using its magnitude which could be either large or small. In the next table, 4 discrete scenarios are presented: gradual or rapid change of large magnitude and gradual or rapid change of small magnitude. A transformation of small magnitude, even if it relates to a disruptive technology, does not consist a disruption in general; thus, it could not be considered disruptive sustainability. A reconfiguration-based transition process operates as opposite to disruption since reconfiguration expresses a distributed multisource system change including cumulative incremental regime change, and on the contrary disruption is a much rare occurrence (Kivimaa et al., 2021).

Disruption in sustainability transitions from the point of view of magnitude and speed of change

Range of magnitude	Gradual change	Rapid change
Large magnitude of change that concerns more than one disrupted parameter	A disruption that occurs incrementally in several steps and ends with the transformation of a whole system	A fast disruption that signals a breakdown of the existed system, and it is of stretch-and-transform type
Small magnitude of change that concerns a single disrupted parameter	Sustaining innovation that further improves existing system configurations	A fast disruption that is pertinent to a disruptive innovation and is of fit-and-conform type

Kivimaa et al. (2021)

Destabilization represents a lose alignment among the several parameters of a sociotechnical system where incumbents gradually reject well-established behaviors, perceptions, principles, and practices. Disruptive sustainability has been related to technologically advanced innovations. Such innovations can suggest solutions to existed problems regarding environment and provide benefits to community and corporations. Disruptive sustainability is not exclusively or solely based on technological advancements. It is more about a general disruption beyond technology which intervenes in multiple parameters of a sociotechnical system, and it is related to multiple changes in several levels of a market including changes in the list of major players, ownership, collapsing of existing business models, etc. (Kivimaa et al., 2021: 10–11).

A change toward sustainability in regulations, policy, and formal institutions concerns a significant transition that is followed by an important number of players in the market and stakeholders. The destabilization is presented as a de-institutionalization process where players follow new metarules signaling a refresh in regulations and a collapse of established barriers. There are two dipoles: incremental versus abrupt change and continuity versus discontinuity as the result of

transformation. Disruption from the institutional point of view evolves a process where an abrupt change causes a collapse of established institutions and their substitution with new ones. Examples of such disruptive sustainability changes in institutional level could be considered the reaction to the Great London smog with the new laws and the European decision for the decommissioning of nuclear power plants. Proportionally, a gradual change of extended magnitude could result in a completed transformation and a discontinuity of established institutions. This is the case with the improvement of transportation system in Finland that included the introduction of the Transport Service Act. In general, a disruptive sustainability change is more disruptive when it leads to discontinuity of an existed model rather than improving an existed model as addition (Kivimaa et al., 2021). For example, in the case of traditional transportation model, the use of biofuels and hybrid or electric cars acts supportively to the existed model putting away the car-sharing alternative model. Several innovations in the same sector do not necessarily lead to disruption. Consequently, in that case, these disruptive changes are toward sustainability in comparison with traditional fuels and transportation emissions, but they do not consist outstanding sustainable disruption comparing with the car-sharing model. Sometimes, the different point of view could lead to different conclusions.

Disruptive sustainability is a transition process that involves three discrete spheres: (a) landscape, (b) regime, and (c) niches. The term landscape describes macroeconomic conditions, environmental parameters, demographic changes, etc. Regime concerns the structure and operation of socio-technical system, incumbent companies, existed technologies, regulations, institutions, practices, etc. Niches refer to spaces where innovations and new ideas are created, tested, and flourished (Geels & Schot, 2007). The main idea is that several landscape actions apply top-down forces, and on the contrary various emerging niches cause bottom-up agitations that in total disrupt, destabilize, and destruct existed regime (Kivimaa & Kern, 2016).

A disruptive sustainable transition consists a creative destruction or destabilizing of old and the development of new (Kivimaa & Kern, 2016: 1). A disruptive sustainability transition cannot be just a mere technology innovation. It should be dissipated in all aspects of a socio-technical system. Thus, disruptive sustainability aims to systemic improvements based either on the continuity or the discontinuity of an existed model, system, market, behavior, practice, institution, etc. Such transitions could take place in the fields of production, consumption, transportation, energy, etc. These sustainable transitions need special conditions to flourish like secured niche spaces for innovations, processes of weakening incumbent regimes, etc. in order to form a window of opportunity for new players, new business models, new practices, etc.

Disruptive sustainability as a process implies the action of destruction of old through destabilization and the born and development of new. (Turnheim & Geels, 2012)

Disruptive Sustainability Policy Mixes

The formation of the proper conditions that could accelerate both opposite actions needs the application of certain policies. In the case of absence of policies that could assist the destruction of established regime, alternative brand new ideas may grow slowly or may be vanished (Kivimaa & Kern, 2016). The policies for the destabilization of incumbent could be either active or passive. A passive approach could be the withdrawal of state support, and on the contrary an active approach could involve prompt changes in regulations and institutions. Thus, a creative policy mix is necessary to boost disruptive sustainability transition.

Moreover, this kind of policy mix needs instruments that support its application in multiple layers. Some models of policy mixes have been developed that are used to welcome the introduction of such changes mainly for noninnovation purposes (Howlett & Rayner, 2007):

- The first model is based on layering, meaning that new targets and instruments could be just

added over the existed ones. Unfortunately, this aggregation of old and new ideas hides controversy and lacks functionality.

- The second model is based on a drift to new targets without replacement of existed instruments. Similarly, there is inhomogeneity between the tools and the goals.
- The third model consists the conversion of instruments without the withdrawal of old targets.
- The fourth model included changes in both instruments and targets by replacing the old with the new (Kern & Howlett, 2009).

Ideally policy mixes for transitions include elements of creative destruction involving both policies aiming for the creation of new and for destabilizing the old. (Kivimaa & Kern, 2016)

Advantages of Disruptive Sustainability for Corporations

Disruptive sustainability could facilitate the transition to a more sustainable form for each company thus toward a more sustainable world in total. Companies are skeptical regarding changes and especially those that demand important resources and could affect their core business. A strategy toward sustainability that is based on disruption could theoretically offer advantages to a company. These advantages should be considered during the decision-making process that is described by the term Operational Ethical Dilemma that has been developed regarding the design and implementation of a Corporate Social Responsibility (CSR) strategy (Panagiotopoulos, 2020). Disruptive sustainability could operate as the flagship of a CSR policy, and any possible benefit could be a reasoning in favor of disruptive sustainability programs. Such potential benefits are (Cochran & Wood, 1984; Maqbool & Zameer, 2018; Mc Williams & Siegel, 2011):

- Increased corporate financial performance (CFP)
- Enhanced reputation
- Better ranking in stock market indices
- Employee satisfaction and loyalty

- Customer satisfaction and loyalty
- Building of relations and trust with stakeholders
- Expanding consumer base with socially and environmentally sensitive citizens
- Elimination of risk for environmental scandals and governmental fines
- Entering new markets
- Green marketing
- Restructuring of processes and economies of scale in long term

A successful disruptive sustainability approach should be based on a transition from a profit-oriented to a socially and environmentally oriented philosophy and could entail several profits for an organization. A massive orientation toward disruptive sustainability from the side of corporations could be amplified by proper governmental decisions that could provide more incentives to them to examine sustainable solutions.

Epilogue

European Union (EU) has designed Green Deal as a European sustainability plan for the well-being and health of citizens and future generations. Indicatively, cornerstones of that are the following (European Commission, 2019):

- The green transition presents a major opportunity for European industry by creating markets for clean technologies and products.
- Renovating our homes and buildings will save energy, protect against extremes of heat or cold, and tackle energy poverty.
- Nature is an important ally in the fight against climate change.
- We can only solve the global threat of climate change by working with our international partners.
- Reducing greenhouse gas emissions by at least 55% by 2030 requires higher shares of renewable energy and greater energy efficiency.

As sustainability is becoming a global demand, disruptive sustainability should be enhanced.

However, such changes could have disadvantages regarding other levels of human welfare, and thus, a disruptive sustainability process is not automatically proper and fruitful. Disruption in technology, policies, institutions, market players and business models, and behaviors and practices should be examined at several levels. Disruptive sustainability should be a multiple level process that covers spherically any impact of a transition (Kivimaa et al., 2021):

- New models and possibly new markets could be born in accordance with new rules, policies, and laws.
- Established barriers should be collapsed for alternatives ideas to be materialized and new practices to be implemented with positive environmental footprint.
- Barriers for newcomers in the traditional markets should be collapsed, and incumbents and institutions should follow the wave of innovation and sustainability.
- The monopoly or oligopoly in ownership of resources cannot promote innovation and alternative thinking. The increased participations of new entrants and small companies could bring a creative change in traditionally operated markets.
- Any reward to alternative thinking that enhances creativity and disruption is welcome.

Disruptive sustainability consists a great challenge for the modern world. However, this transition should be made in a smooth way to mitigate any side effects and collateral damages like lack of training in new technologies for employees, unemployment, energy instability, technological accidents, etc. Proper preparation and willingness for adaptation are essential elements for a transition toward a more sustainable world where states, companies, and citizens are all participants.

Summary

The modern call for Sustainability could be complicated having both positive and negative impacts for companies and society. This kind of

transformation to a more sustainable world may need Disruptive Sustainability elements since there is not plenty of time for saving our planet. Disruptive Sustainability could be the way to boost the global reorientation toward sustainability worldwide. Disruptive Sustainability marks a transition process that has specific dynamic characteristics that differentiate it from other kinds like Disruptive Innovation or Sustaining Innovation. Disruptive Sustainability embraces a transformation process that starts with the destruction of the already existed status in a socio-technical-economic system and produces a more sustainable situation due to the resultant of many forces that pulling finally toward Sustainability.

Description

Diversity initiatives and management have become an important business imperative for the workforce of the twenty-first century (Roberson 2006). The traditional workforce, which was dominated by white, male workers, has started to shift by inclusion of females, minorities, ethnic groups, and workers with international origin. Organizations have understood the importance of diversity and inclusion matters and if managed effectively, their potential impact on the overall business performance.

Diversity is a concept that represents a variety of differences and similarities that exist among individuals (Wellner 2000). Four layers of diversity model as laid out by Gardenswartz and Rowe (2003) illustrate the different characteristics representing diversity. These four layers are: (1) organizational dimensions, (2) external dimensions, (3) internal dimensions, and lastly

(4) personality. Figure 1 illustrates the four layers of diversity model by Gardenswartz and Rowe.

The outer layer of the model, which represents organizational dimensions, includes functional attributes, management related attributes, union association, workplace, seniority, department unit/group, and work content.

External dimensions layer consists of geography, marital and parental status, appearance, work and educational background, religion, recreational and personal habits, and income.

Internal dimensions layer consists of age, race, ethnicity, physical ability, sexual orientation, and gender.

According to Washington (2008), organizational dimensions are characteristics where organization has some influence. External dimensions represent choices of the individuals or employees such as their life choices, preferences, and beliefs. Internal dimensions are mostly given by birth. And finally, personality traits imply consistency and stability and reflect people's characteristic patterns of thoughts, feelings, and behaviors (Diener and Lucas 2019).

Diversity, Sustainability, and Corporate Social Responsibility

The notion of diversity and its positive impact on sustainability is not free from debate. Penrose and Penrose (2009) states that each firm gets its unique character from the heterogenous nature of its productive services available. However, Van Knippenberg and Mell (2016) emphasize on the dual impact of diversity on group decisions. On the one hand, diversity encourages different opinions and serves as a catalyzer when making group decisions. On the other hand, diversity could cause frictions among people and hinders the group harmony. Although this debate has existed in prior literature, it is observed that successful execution of diversity management can generate synergies for the companies, create new opportunities, and even improve the innovation culture.

Innovation is an iterative practice that includes contact and interaction among the employees of the companies (Østergaard et al. 2011) and has

Diversity, Fig. 1 Four layers of diversity model by Gardenswartz and Rowe (2003)

strong ties to diversity. Østergaard et al. (2011) found out that employee diversity influences the likelihood that firms innovate and that diversity aspects cannot be ignored when assessing a firm's innovative capabilities.

Other important governance issues of today's corporate world are the composition of board of directors since board diversity can have significant implications on shareholder value. Carter et al. (2003) studied the nexus between board composition and company value for Fortune 1000 companies and indicated that there are important positive relationships between portion of women and minorities and of company value.

In addition, there is vast body of research regarding diversity management and corporate social responsibility (CSR). As a matter of fact, diversity management and CSR initiatives are often executed alongside one another (Maj 2018). CSR often serves as an umbrella for diversity initiatives (Maj 2017). When reporting corporate social responsibility, companies have utilized different methods of reporting such as "triple bottom line" or Global Reporting Initiative (GRI) (Dawkins and Ngunjiri 2008). Diversity has been a key dimension of corporate social repositionability reporting of the companies. Vast body of CSR research has utilized the Kinder

Lydenberg and Domini (KLD) ratings for CSR (Graves and Waddock 1994; Johnson and Greening 1999). KLD dimensions consists of (1) Environment, representing the impact on ecosystem, (2) Community, representing various contributions to wellbeing of the community, (3) Diversity, representing inclusion and advancement of minority populations, (4) Employee relations, and (5) Human rights (Dawkins and Ngunjiri 2008).

Summary

As mentioned earlier, diversity management has become an important business imperative in today's workforce environment and can be a key to growth in today's competitive environment, if managed well.

However, it is important to evaluate diversity within the context of geography. As a matter of fact, predominant diversity issues in each country may be different (Shen et al. 2009). Dimensions of diversity in western cultures can be significantly different from the dimensions of diversity in eastern cultures.

Effective human resource diversity management activities with recruitment, selection, training, and performance management of employees can enable good diversity practices in firms and eventually contribute to business performance. According to Shen et al. (2009), there is a continuing need for effective diversity management and Human Resource Management (HRM) plays an irreplaceable role in this regard.

Definition

Diversity relates to a complex concept encompassing various dimensions that may interweave to generate unique syntheses of human profiles, in various contexts, circumstances, and environments. Diversity management refers to the implementation of diversity in a company's day-to-day learning and managerial processes. It entails the activation of a managerial and communicative process that rests on accepting and leveraging on employees' and collaborators' similarities and differences that are considered as potential in an organization.

Introduction

Diversity has been conceived as “any mixture of items characterised by differences and similarities” (Thomas 1996, p. 5) tied to several dimensions (Loden 1996), including gender, ethnicity, age, physical qualities/abilities, sexual orientation, and race (Thomas and Ely, 1996). Additional dimensions (called “secondary dimensions” since they are less visible than the main dimensions) encompass native language, communication style, educational background, family history, religion, parental and marital status, work experience, income, and geographic location, among others. Moreover, tertiary dimensions comprise features such as beliefs, assumptions, perceptions, attitudes, feelings, values, and group norms (Rijamampianina and Carmichael 2005; Jirincova 2013). At the institutional level,

the EU has established six main dimensions (gender, age, disability, race and ethnicity, religion, and sexual orientation), while features such as education, profession, and family status have been included in the secondary dimensions.

According to these features, diversity management deals with the ways a company strategically manages the aforementioned dimensions of diversity in carrying out the activity, integrating practices and programs within the internal and external environment.

Diversity management rests on the awareness that a diverse workforce elicits creative potential useful to reconcile cultural boundaries and look for original solutions, innovative product concepts, and marketing proposals, thus increasing competitiveness and companies' resilience. Indeed, diversity management generates added value since it allows the organization to internalize differences among employees and collaborators by enhancing the unique contribution of each person to organizational purposes and strengthening the company's capability to face challenges and uncertainty.

Diversity management was first developed in the early 1990s in the United States, where large companies, called to manage a multi-ethnic population, first tackled the problem to improve the talent, skills, and competences of collaborators belonging to different races, religions, and backgrounds (Pless and Maak 2004). Over time, both the concepts of diversity and diversity management have progressively evolved, broadening the field of management of women and minorities in the workforce and gaining momentum in management theory and practice, thus overcoming the initial focus on demographic and legal aspects (i.e., the avoidance of laws for women and minorities).

In recent decades, both globalization and demographic changes have increased the diversity of the population and labor force. As a consequence, the issues of inclusion and diversity represent key points of both the political and business agenda.

In 2000 the EU released two directives to fight discrimination (Keil et al. 2007), respectively aimed to grant equal treatment regardless of racial

or ethnic origin (Council Directive 2000/43/EC; EC 2000) in the areas of education, employment, health care, social security, and access to goods and services (Keil et al. 2007), and to establish a framework for the unbiased management of employment and occupation concerning religion or beliefs, age, sexual orientation, and disability (Council Directive 2000/78/EC; EC 2000). Subsequently, every member country established its own national anti-discrimination law.

The European Commission (EC 2003) pointed out the benefits of diversity, emphasizing the growth in the organizational culture, the corporate reputation, and the attractiveness and retention of highly talented individuals, as well as improvement in productivity, innovation, and creativity.

Several studies have highlighted that the challenges triggered by global markets' increasing demand for innovation, creativity, and flexibility can be best fulfilled by the broadened pool of knowledge and experience found in a diverse workforce that is effectively managed (Cox and Blake 1991; Milliken and Martins 1996). In a globalized economy, a growing number of companies recognize the opportunities deriving from a multicultural workforce and are interested in promoting inclusive work conditions (Cox 2001).

Diversity management is based on an inclusive-oriented approach to management and governance. The culture of inclusion is fundamental to create an organizational culture where individuals from different backgrounds are committed to achieving common goals resting on the pillars of diversity management inclusiveness, integrity, and challenging assumptions and mindsets. In this vein, the founding principles of a human relations management system should include treating others with respect, acknowledging others and appreciating different opinions; encouraging participative decision-making and problem-solving processes; and demonstrating integrity and ethical reasoning. To put into practice these pillars and principles a consultative leadership style is necessary, as well as specific tools such as training programs, mentoring team development, and ongoing workshops. Inclusiveness requires encouraging people from different cultural backgrounds to share their experiences, knowledge, and standpoints, and also requires

trust, moral reliability, and coherence (Gilbert et al. 1999). The creation of an inclusive organizational environment implies a cultural change process to foster the creativity and innovation potential of a diverse workforce.

Competencies nurtured by the aforementioned founding principles and managerial tools translate into observable and measurable behaviors, such as recognizing other people as different but equal; active listening and trying to comprehend disparate points of view and opinions; incorporating different voices into the ongoing cultural discussion; improving team capabilities; and demonstrating integrity and advanced ethical reasoning, especially to tackle ethical dilemmas (Matthews 1998).

Several authors have suggested conceptual models useful to examine the antecedents and consequences of effective diversity management (Gilbert et al. 1999), while others have addressed attention to the process to effectively manage diversity (Cox and Beale 1997) and lead change (Kotter 1996). The graph below depicts the main steps (Fig. 1) that are necessary to implement an inclusive diversity culture through raising awareness of inclusion, establishing a vision of inclusion, reconsidering key management principles, and revising systems and processes.

In the first step a project team (i.e., the diversity steering committee) should be set up including people from diverse backgrounds. The company's goals to implement diversity should be defined in collaboration with the diversity steering committee. The goals should ensure the participation of all relevant divisions/areas/departments and define clear measurable criteria for achieving them.

The company's top management and key stakeholders should be supported by external consultants in delineating different scenarios of the business context from a long-term perspective.

Both the company vision and mission should be reframed and shared in accordance with the selected scenario, and the strategy should emphasize the way diversity management could be operationalized.

In a subsequent step, a diversity audit based on interviews addressed to stakeholder groups is useful to outline the appropriate actions for change.

Source: synetz – the management consultants www.synetz.de

Diversity Management, Fig. 1 Diversity management implementation. (Source: Keil et al. 2007, p. 14)

Finally, the process should be operationalized through the diversity team-building functions execution, the top/middle management leadership development programs; and the adoption of performance management appraisal tools useful to assess the diversity management outcome (Gen- tile 1994; Gardenschwartz and Rowe 1998).

A specific training manual for diversity management has been developed under the framework of the European Community Action Programme to fight discrimination and advocate for anti-discrimination legislation across the European countries (Diversity Training VT 2006/009 project; Keil et al. 2007). The guidelines point out that the involvement of the top leaders is fundamental to develop effective diversity management actions and create the conditions (Table 1) to become a successful diversity-oriented company.

The guidance was designed to accompany the diversity management components of the project in the European countries, as well as the managers and staff of employers’ organizations and practitioners.

Specific attention has been addressed by the EC to small and medium-sized enterprises in order to increase their awareness on diversity issues and contribute to filling in the gap for information and training (Table 2).

Without making a significant investment in both time and human resources, companies cannot fully embrace the valuing diversity paradigm.

Diversity Management, Table 1 Enabling conditions for diversity management

A clearly devised company strategy and vision, encompassing diversity as a long-term economic resource
Leaders’ awareness of the key role of diversity within the company mission
A transparent performance management system, shared by internal stakeholders
Teams nurtured by a set of competencies, talents, experiences, and personal attributes that facilitate innovation and creativity
Performance-based staff evaluation systems, aimed to avoid any discrimination
Innovative recruitment system, aimed to assess and encourage talented and diverse people

Source: Author’s elaboration

However, the efforts spent are counterbalanced by several benefits, including enhancing the cultural mix; improving market opportunities; strengthening external recognition and image; and enhancing organizational capital (Gilbert and Ivancevich 2000; Roosevelt 2006).

Key Issues

Discriminatory attitudes and behaviors in the workplace still represent major obstacles in developing diversity strategies and practices. As a

Diversity Management, Table 2 Diversity management implementation in SMEs

Steps	Contents
Analysis	Analysis of an SME's strengths, weaknesses, and issues
Recruitment	Decisions aimed to match job roles and staff profile, avoiding personal values and convictions in order to reduce turnover and increase staff retention

Internal communication	Adoption of internal communication systems aimed to increase exchange of ideas, knowledge, and perspective and increase staff commitment
Image and reputation	Use diversity commitment as a tool to improve reputation and strengthen public relations policies
Evaluation	Assess costs and benefits of diversity policies
External support	Adoption of external consultants to strengthen diversity processes implementation within human resources management

Source: Our adaptation from Keil et al. (2007)

result, for many companies, approaches to raise awareness about diversity issues and policies are an essential part of the implementation of diversity management policies. Leveraging diversity requires a shift in assumptions about the organization's culture. Diversity impacts the management system at several levels of the organizational processes (motivational, interaction, visioning, and learning processes) (Rijamampianina and Carmichael 2005).

Drawing from the business cases included in the European project, some common features emerge as enabling factors, including the change of human resources management systems, the use of training programs, and the implementation of

support structures (EC 2005). The areas affected by the change of organizational factors encompass recruitment selection retention (i.e., employees' development and promotion), leadership development talent, employee networks, and community engagement. Moreover, effective management approaches rest on internal training initiatives useful to develop awareness of stereotypes and prejudices (e.g., the assumption of mobility as a rewarding factor for a successful career) and increase managers' competencies in diversity management, as well as the implementation of work-life balance projects, job sharing, and flexibility, and the adoption of policies to allow employees to take care of children and relatives, permits, and parental leave (Auen and Montgomery 2001).

Summary

To attain a sustainable growth, businesses must consider and manage the full potential that diversity can offer. Diversity and inclusion practices contribute to improving managerial skills, communication, and information-sharing; more generally they improve human capital and enhance market opportunities, external recognition, and image, thus raising companies' standing in society (i.e., developing partnerships with research institutions and NGOs, entering equality and diversity awards).

In Europe there are several successful examples. For instance, in 2006, some German companies started a voluntary campaign ("Diversity as a Chance") through the implementation of a charter of diversity aimed to create a work environment free of prejudice and a corporate culture focused on mutual respect and recognition of every individual (European Commission, EC 2005). Similar initiatives have been implemented in other countries, resting on the conviction that the promotion of diverse potentials yields economic benefits, generates positive effects on the company's reputation, and has a positive effect on the whole society.

In this vein, the dissemination of good practices is useful not only to explore opportunities and obstacles, but also to share good experience that allows companies to foster diversity management.

Diversity of Boards

Sadi Boğaç Kanadlı¹ and Nada Kakabadse²

¹Republic of Turkey Ministry of Trade, General Directorate of Customs, Çankaya, Ankara, Turkey

²Henley Business School, University of Reading, Henley-on-Thames, UK

Definition

Corporate boards are viewed as the upper echelons of their firms, performing the critical tasks of overseeing and influencing the strategic actions of the firms. While controlling managerial decisions

and actions are fiduciary responsibilities (control tasks) of boards, they also participate and contribute to strategy process by providing advice and counsel (advisory tasks), initiating strategic proposals, and contributing to the implementation of strategic decisions (strategic tasks) (McKinsey 2016). How to enhance boards' performance has become a critical question for scholars, corporate leaders, and policymakers. In answering this question, this chapter focuses on the importance of board diversity with regard to directors' different functional backgrounds, educational backgrounds, and industry experiences. Whether such variety in the boardroom benefits the strategic actions of firms or not is considered. The chapter also addresses a greatly neglected issue which has enormous practical importance: the boardroom barriers. There are social, power-related, and cognitive boardroom barriers, which might limit the utilization of board diversity. When these boardroom barriers are acknowledged, a complementary question remains: how do scholars, corporate leaders, and policymakers make board diversity work?

Introduction

"Whether and how corporate boards affect organizational outcomes" is still one of the key questions in corporate governance and, to some extent, strategic management, which has continued to be relevant through the decades (Zahra and Pearce 1989; Krause 2017). However, recently it seems this inquiry is becoming more focused. Diversity is, slightly but steadily, increasing in the boardrooms (Catalyst 2018; Deloitte 2019). Corporate leaders are aiming to create diverse boards, expecting them to actively participate and contribute to the strategy process (Fairchild 2015). A recent survey of "The CEO Guide to Boards" by McKinsey (2016) revealed that strategy is, on average, the area to which boards give most of their attention. Accordingly, whether and how board diversity influences the strategic decisions of firms has become a timely and important topic which has enormous practical implications. But what is board diversity?

Although it is hard to provide a common definition of diversity in boardrooms, diversity simply means "variety" (Milliken and Martins 1996). Variety in boardrooms is commonly viewed as variety in directors' knowledge, skills, and professional experience, which is a reflection of directors' different functional background, educational background, and industry experience. However, "variety" is also referred to as "board heterogeneity," "knowledge/information diversity," "cognitive diversity," and "job-related diversity." From a practitioner's viewpoint, variety in boardrooms means the availability of a broader pool of relevant information and expertise and an increased number of perspectives on the strategic issues at hand (Fairchild 2015; McKinsey 2016). Using this information and evaluating different perspectives, diverse boards may contribute to the creation of strategic decisions more effectively and with more creativity (Rindova 1999). How?

Corporate leaders' initiatives in creating variety in boardrooms find considerable support in research, such that directors' different skills, knowledge, and professional experience enhance boards' ability to successfully perform board tasks (e.g., Kakabadse et al. 2018; Gabaldon et al. 2018) as well as their contributions to strategic decisions (e.g., Haynes and Hillman 2010). Research also demonstrates that such variety helps firms take better quality decisions (e.g., Sun et al. 2015) with a higher degree of creativity (e.g., Torchia et al. 2018).

However, while board diversity may mean variety in directors' skills, knowledge, and professional experience, at the same time, it may also mean separation and disparity (Harrison and Klein 2007). This is a critical specification as it introduces boardroom barriers in the discussions about whether board diversity benefits strategic decisions. For example, increasing numerical representation of women on boards has become a worldwide issue, and it seems investments of policymakers, institutional investors, as well as nongovernmental organizations (NGOs) to this end have been paying off (Catalyst 2018; Deloitte 2019). Women directors have different values (Eagly 2016; Post and Byron 2015) and different

knowledge and experience (Hillman et al. 2002; Singh et al. 2008) compared to their male counterparts. From this perspective, an increasing number of women on boards can be expected to increase variety in boardrooms, which might positively impact boards' contribution to strategic decisions. Indeed, this is one of the main economic arguments, which finds empirical support (e.g., Torchia et al. 2018; Triana et al. 2013), put forward by defenders of an increasing number of women at upper echelons. This line of thinking views gender diversity as a variety.

However, gender diversity can also mean separation, which may result in out-group/in-group or we/they separation in the boardroom (Harrison and Klein 2007). Gender is generally a salient observable among upper echelons, which can lead to the automatic and instant out-group categorization of female directors (Zhu et al. 2014). Out-group categorization of women directors in male-dominated boards (Groysberg and Bell 2013) might limit women directors' contributions to board decision-making and, accordingly, strategic decisions (e.g., Huse and Grethe Solberg 2006; Kakabadse et al. 2015). *From this perspective, whether and how variety influences strategic decisions can be better understood and explained when social barriers are taken into account.*

Likewise, board diversity may also mean variety and disparity. For example, it is not unusual to describe boardrooms as an arena for power games where representatives of major shareholders (i.e., directors with friendship ties to the CEO) or a set of white, male, experienced directors dominate boardroom discussions (Finkelstein 1992). Such asymmetric power held by the few in boardrooms results in the asymmetric use of resources, from information about financial reports to organizing informal meetings or social gatherings. Those few directors may be enriching variety in the boardroom but also creating high levels of disparity, by just those few benefiting from all resources. How would such power asymmetry impact the utilization of directors' different skills, knowledge, and professional experience? Research suggests that the presence of a high-power individual (e.g., Haynes and Hillman 2010) or power imbalance between directors (e.g., Triana et al. 2013) may

hinder boards' contribution to strategic decision-making. *From this perspective, whether and how variety influences strategic decisions can be better understood and explained when power-related barriers are taken into account.*

Considering how diversity may mean variety, but also separation and disparity, implies that there are social and power-related boardroom barriers that may limit the full use of directors' diverse talents on strategic decisions. However, the scholarly discussions and practices in policy and the corporate world are still centered on the questions of whether there should be more diversity in boardrooms and whether variety in directors' skills, knowledge, and professional experience benefits firms. Considering the research that provides considerable evidence in support of this variety and acknowledging the presence of boardroom barriers, there are two emerging questions, specifically, what the barriers are that limit the use of directors' diverse talent and how to make board diversity work.

Key Issues: Boardroom Barriers

Specifying board diversity as variety, separation, and disparity reveals two boardroom barriers that might limit the utilization of directors' different skills, knowledge, and professional experience on board tasks and, thus, on strategic decisions. A third boardroom barrier could be added to the list which rests on the idea that directors are expert decision-makers with unique knowledge and expertise, but they also have limited cognitive capacities. To be able to generate solutions to reduce or avoid the negative consequences of these boardroom barriers, the first step is to better understand the processes and mechanisms that create these obstacles, as well as their negative consequences.

Social Boardroom Barriers

Social categorization perspective, which incorporates social identity and self-identity theories and the similarity/attraction paradigm, explains the processes that lead to out-group/in-group or we/they separation in groups. Social categorization

perspective posits that individuals create and define their own place in society by categorizing themselves in social groups with some emotions and values significant to them regarding the group membership (Van Knippenberg et al. 2004). When a certain observable is salient (e.g., gender), out-group categorization tends to be automatic and instant (Gaertner et al. 1989). This leads to intergroup bias which refers to more favorable perceptions of, and attitudes and behavior toward, the in-group than the out-group (Van Knippenberg et al. 2004). As a result of intergroup bias, evaluations are based on category (e.g., woman versus man) rather than individual merit; negative attributes are exaggerated, and positive ones can be discounted; and permissible behavior of the stereotyped person is clearly constrained (Fiske et al. 1991).

Research has shown how the negative consequences of out-group categorization may impact group dynamics (Zhu et al. 2014). People cooperate more with in-group members compared to out-group members; out-group members are at a significant disadvantage for receiving rewards and positive evaluations compared to in-group members. Out-group members are less likely to be noticed for their positive behaviors, but they are more likely to be blamed for negative results. They are thus more likely to be perceived as less competent, and their knowledge and opinions are perceived as less relevant and credible. All in all, diversity's potential cannot be fully realized when some group members face the negative consequences of out-group categorization.

Directors are not immune to social categorization processes (Groysberg and Bell 2013), and gender, age, ethnicity, education, functional background, top executive experience, and industry background are salient features among directors (Zhu et al. 2014). Based on these factors, women directors can be instantly and automatically categorized as out-group members by a male director majority. Observable differences (e.g., gender) are at the center of discussions on social categorization processes because they are simply easy to observe and used as heuristic cues by group members to categorize themselves and others into similar in-groups and dissimilar out-groups. As a

matter of fact, when it is realized that there might be several subgroupings based on aforementioned salient features in the boardrooms, one important issue emerges – the demographic fault lines in boardrooms (Kaczmarek et al. 2012). Demographic fault lines are defined as hypothetical lines that divide a group into multiple subgroups based on the alignment of salient attributes (Lau and Murnighan 1998).

In this regard, diversity as separation can be better understood when the existence of board demographic fault lines are acknowledged, rather than only focusing on observable salient features. In turn, while board demographic fault lines can explain the subgroupings in boardrooms, out-group/in-group categorizations can be used to explain negative consequences of subgroupings on board performance (Kanadli et al. 2018; Westphal and Bednar 2005; Veltrop et al. 2015). One interesting point is that social categorization processes are automatic and instant particularly when the salient feature is observable. However, it should be noted that both board demographic fault lines and negative consequences of out-group categorization require activation.

Not all demographic fault lines can be expected to affect board functioning. If board demographic fault lines are activated – when they lead to the perception that the board is split into subgroups – board performance can be expected to be negatively affected (Veltrop et al. 2015). For example, following a merger and acquisition ((M&A) when firm A acquires firm B), the newly formed board can welcome women directors (from firm B), and a subgrouping may be observed based on gender (women directors versus male directors) in the board of the newly formed organization. Interestingly, the subgrouping may not be based on gender but rather on a division between newcomers and hosts. Additionally, if newcomers (firm B) are all younger directors than the hosts (firm A), a strong fault line could be detected, which can be expected to activate the perception of subgrouping in the newly formed board. In this stage, social categorization can be thought to occur in the boardroom: “we,” “they,” “in-group members,” or “out-group members.”

However, such instant and automatic out-group categorization does not imply per se that the aforementioned negative consequences of intergroup bias will be realized on out-groups (Van Knippenberg et al. 2004). Intergroup bias is typically inspired by threats or challenges to the value or the distinctiveness of group identity. For example, challenges can be social competition for status and prestige, outright derogation and discrimination of the group, and unequal status of subgroups and competitive interdependence between subgroups (Van Knippenberg et al. 2004). Following the M&A example, negative consequences of out-group categorization on newly appointed young directors can be felt when existing tenured directors perceive newcomers' behaviors and attitudes as a challenge or threat. The ability to operate effectively as a board, sharing unique information and communicating perspectives, becomes more difficult because the board is separated into salient subgroups (Li and Hambrick 2005).

In summary, without considering the effects of social barriers, any conclusion on the influence of board diversity on boardroom decision-making may be misleading.

Power-Related Barriers

The second set of boardroom barriers, which can be once again expected to limit directors' use of their diverse talent, refers to the "silencing impact" of power asymmetry felt by low-power directors in the presence of a high-power individual(s) (Pearce and Zahra 1991). A high-power individual in the boardroom is defined as someone who has the capability of overcoming resistance in achieving a desired objective or goal (Finkelstein 1992). A CEO or a chairperson will have such a capability, mostly because of their structural power (Finkelstein 1992). A CEO, being the leader of a firm, as well as a chairperson, being the leader of the board, can be specified as high-power individuals in the boardrooms, having structural power.

In boards where there is CEO duality structure (as is quite typical in the USA), a CEO might also be a chairperson in the board, enhancing his or her structural power. However, it is hard to claim that

this is the dominant structure across the corporate world and, hence, a CEO can often only attend board meetings as a chair. Non-duality may be a common practice in boards (particularly in Europe), and a CEO might be in the boardroom as a board member (Kakabadse and Kakabadse 2007). In the single structure board, there might be several reasons for the CEO to be present such as to answer questions regarding the issue under consideration. For example, a CEO can be the main bridge to, or communication channel between, the top management team and the board. Moreover, relatedly, a CEO may be the main possessor of firm-specific information as well as the knowledge that is essential for competent board work. In addition, a CEO might personally prefer to be present during board meetings, with the aim of controlling discussions and any possible rivalry to his/her leadership in the firm.

While most discussions on power focus on CEO duality and thus structural power as the source of power in boardrooms, there are other sources of power that should be considered, particularly with a view to understanding power asymmetries between directors in boardrooms. Finkelstein (1992) established four types of power: structural, ownership, expert, and prestige, each of which is pertinent to the board of directors. Structural power is rooted in formal position and hierarchical authority and indicates the human capital required for the job. Ownership power is related to equity ownership as well as founder status. A director possesses this power when he/she represents the will of the shareholders. Expert power can develop as a result of having exposure to many different functional areas and breadth of assignments as well as through organizational tenure or years of experience, indicating the task and job knowledge of the director. Prestige power develops from one's institutional environment based on personal prestige or status, reputation, and perceptions of influence (Finkelstein 1992). Prestige power may develop as a result of having a position on one or more boards, serving on influential committees, or having attended elite educational institutions (Finkelstein 1992), suggesting a certain level of knowledge and connections.

Accordingly, a tenured director who holds membership of nomination and/or compensation committees and multiple board appointments may in turn be perceived as high-power individual in boardrooms. Specifying power asymmetries in boardroom matters as a high-power individual may intentionally or unintentionally exert a “silencing effect” on the directors with lower power (Pearce and Zahra 1991). In teams with mixed-status individuals, the high-status individuals speak more and tend to exert influence over team discussions (Cleveland et al. 2000). In a board context, research shows that a powerful CEO may silence the different voices of directors during board discussions (Haynes and Hillman 2010). Women directors are considered to have lower power than their male counterparts because they are in general younger, lack committee memberships and top executive experience, and have held few or no multiple board appointments (Triana et al. 2013). Triana et al. (2013) show that only when women directors have power in male-dominated boards can they influence strategic decisions.

Power asymmetry in boardrooms can also be linked to age diversity, one of the emerging topics in the corporate world. The main idea is that firms should engage more and more in the use and adaptation of new technologies, which may require the appointment of young directors to boards. New generation of younger directors around the age of 40 (compared to average age of a director, 55–60) are thought to be better facilitators for adapting the latest technologies. However, it is highly likely that these younger directors lack the experience as a director, may not hold committee memberships, or have had multiple board appointments. Are boards really ready to utilize such low-power young directors’ talents in the presence of high-power individuals? Although research is limited, to date the answer seems to be equivocal (Ali et al. 2014).

In summary, without considering the effects of power-related barriers, any conclusion on the influence of board diversity on boardroom decision-making may be misleading.

Cognitive Barriers

It might be surprising to acknowledge that for almost half a century, and to some extent even now, the dominant theories of corporate governance have adopted a model of individual who is assumed to be rational (Ghoshal 2005). In other words, directors are assumed to be superheroes who have all the information to objectively make a decision that would maximize shareholders’ profit. Of course, there are alternative perspectives taking prominence positing that decision-makers are only of a limited (bounded) rational. The concept of bounded rationality refers to the notion that decision makers in organizations experience limits in their ability to process information and solve complex problems. (Van Ees et al. 2009). In this regard, like other individuals, directors have limited cognitive capacity in processing information. Boundary conditions of information overload occur when individuals reach a point at which they are unable to process any additional information (Tushman and Nadler 1978). Not recognizing that a director or board as a whole has limitations in absorbing and processing new information may result in the limited use of directors’ diverse talents as those directors may simply reach information overload (Khanna et al. 2014).

In this regard, perhaps one of the most important issues in the corporate world is board interlocking directorates. “An interlocking directorate occurs when a person affiliated with one organization sits on the board of directors of another organization” (Mizruchi 1996, p. 271). It is not surprising that having multiple board appointments is seen as a source of prestige power among directors. Interlocking directorates have been interpreted as an important source of professional experience, timely and relevant information, and diverse perspectives (Shropshire 2010). Therefore, board interlocks reveal some beneficial effects on strategic decision-making (e.g., Hambrick et al. 2015) as well as a diffusion of corporate practices (e.g., Tuschke et al. 2014). As mentioned, board tasks are complex and highly cognitive tasks which are surrounded by ambiguity, uncertainty, and volatility. How many boards a director can efficiently serve on, while absorbing unique information,

processing this information to produce individual perspective, and actively participating in board discussions about the strategic issues at hand?

Board interlocks create “a potential paradox whereby a focal firm benefits, on the one hand, from having access to greater amounts of information through its directors’ networks, but suffers, on the other hand, because of the high cognitive commitment this places on the directors, which limits their ability to effectively monitor and participate in the strategic decision-making process” (Khanna et al. 2014, p. 564).

There is also evidence that highly interlocked boards (at least half of the board members have more than three board appointments) may fail to effectively perform board tasks (Kaczmarek et al. 2014).

All in all, acknowledging social, power-related, and cognitive boardroom barriers, it would be unrealistic to expect the utilization of board diversity on the strategic actions of firms. Once the negative influence of these barriers on the utilization of directors’ different skills, knowledge, and professional experience are acknowledged, the question emerges of how to make board diversity work. Corporate leaders, policymakers, as well as board members can all take steps in dealing with boardroom barriers.

Future Directions: Dealing with Boardroom Barriers

Dealing with Social Barriers

Maybe the most important actor in dealing with social boardroom barriers is the chairperson. So, the first step would be the deliberate selection of a chairperson by corporate leaders. In specifying the leadership attributes of such a chairperson, policymakers and scholars would play a critical role. In some national context, policymakers have already been drawing a chairperson profile such that regulations, as well as best practices of board leadership, require the appointment of independent chairpersons (Kakabadse and Kakabadse 2007). Additionally, research shows that a chairperson with strong leadership efficacy generates

an open and safe boardroom and facilitates board discussions in a manner that encourages directors to actively participate and contribute to board discussions (Gabrielsson et al. 2007; Kanadlı et al. 2018). Leadership efficacy consists of certain behaviors, such as leading discussions, motivating and connecting each board member to best utilize their competencies, formulating proposals for decisions, and summarizing conclusions after board negotiation (Kanadlı et al. 2018). In this regard, a chairperson can be a key beneficiary of the variety in the boardroom while dealing with the results of out-group categorization in boardrooms (separation).

Dealing with Power-Related Barriers

It is common sense that to deal with power asymmetries in boardrooms, power should be decentralized. To this end, the selection of new directors can be one important step that might be taken by corporate leaders. Woman directors might be selected not only for compliance purposes to meet legal obligations (e.g., a gender quota was implemented in 2008 in Norway) but also for their competencies that may be a source of ownership, expertise, and prestige power. Additionally, newly appointed women directors can be simultaneously appointed to important committees, which would also increase women directors’ power in boardrooms. Even policymakers may have a stake in this. Making mandatory, nonfinancial disclosures on the gender profile of boards might maintain more transparency in board nominations, which might provide a source of prestige power for newly appointed women directors.

Moreover, the balancing of power can be complemented – or, in the case of power balancing becoming a problem, replaced – by specifying board norms that would aim to regulate the flow of resources to all directors irrespective of their level of power. For example, there might be a clear division of labor in board functioning and specific rules about the decision-making culture that can be characterized by inclusiveness, collaboration, and openness. It might be possible for a director to personally have access to a manager to

be able to get extra firm tacit knowledge without consulting the CEO or high-power individual who creates disparity in the boardroom. Board evaluations may also work in the same direction, neutralizing the impact of power asymmetries, by incorporating individual evaluations and evaluations of board work as a whole. Policymakers can play a critical role by demanding the disclosure of board evaluations, if not disclosed voluntarily by corporate leaders. All in all, decentralizing power in boardrooms and/or specifying board norms about accessing resources and board decision-making can be key to utilizing the benefits of variety in boardrooms while dealing with power asymmetries (disparity).

Dealing with Cognitive Barriers

Once again, corporate leaders may be careful in setting the criteria for selection of new directors, limiting the number of board interlocks a candidate director, chairperson, or even CEO may have. The search firm Stuart Spencer documented a recent trend (2013) that more and more companies prohibit their CEOs or other executives from sitting on other firms' boards. Moreover, it is not only companies that developed a negative attitude against multiple board appointments but also policymakers (e.g., FRC 2008, 2018; HM Treasury 2009).

In addition to limiting the information-processing demands of nonexecutive directors, relevant information shared by directors before board meetings can be also managed by the use of IT systems: instead of reading pages of reports, book records, and analysis, a specific IT system can be designed to serve the directors' needs, providing refined, tailored information out of the available vast amounts of data and information. Lastly, the number and length of board meetings might be carefully designed, and the chairperson might take responsibility for observing whether information overload is reached during board meetings. In summary, limiting the number of board appointments, benefiting from IT systems' ability to identify salient information, and managing the number and length of board meetings can be key to utilizing the benefits of variety in directors'

diverse talents without causing information overload for each director as well as the board as a whole.

Summary

Although there has been slow but steady progress toward boardroom diversity, it is unclear to what extent a diverse board makes use of the available talent. It all depends on the chairperson's skill and capability to harness the benefits of diversity in the boardroom. Board appointments and dynamics remain largely a black box as not much research have been done on the selection and appointment process in capturing diverse director's experiences as directors. It is usually the chairperson who spearheads the process of making the board a place that values the diversity of functional background, educational background, and industry experience. However, many boards are also recognizing the distinction between diversity and inclusiveness. Where diversity is counting the numbers, inclusiveness is making the numbers count. In order to be sustainable, boards need to improve on both dimensions and, in particular, overcome boardroom barriers – whether they be social barriers, power-related barriers, or cognitive barriers – in order to harness the talent of a diverse board.

Definition

A dividend is defined as a payment made by corporations to its shareholders. It represents the distribution of the company's profits and rests on the principle of maximizing the wealth of shareholders (Baker et al., 2002). The profits generated by the company can be used in several ways – 1) it can be reinvested in the company (retained earnings) in the form of funds invested in new technologies, financing mergers, and acquisition, or 2) it can be retained in the form of cash reserves (deposits) to secure the future of the company. Retained earnings make for an important source of internal finance to the long-term growth of the company, while dividend payouts reduce the funds available at the company disposal.

Profit or a proportion of the profit can be also distributed to shareholders as cash payment or in the form of a dividend reinvestment plan as shares of stock, or other property. The dividend payout is the decision of the board of directors. The payment is distributed to shareholders on the basis of the class of shares owned.

The firm's propensity to pay dividends and the patterns of the payouts are one of the most dynamically developing themes in the finance literature. Analyses aim to explain the determinants of dividend policy in the institutional environment, e.g., investor protection increases the propensity to pay. Such determinants are also noted in the organizational context including the size of the company, its ownership structure, or composition of the board.

Dividend as the Return on Investment

Dividend Payments

Dividend is a payment to shareholders who possess stakes in the company. The underlying logic behind dividend payment is the shareholder expectation to enjoy the return of their investment (Baker et al., 2002; Vermalen, 2009). A shareholder has potentially two options to be compensated for providing funds for the company development.

The first way to enjoy the increase of wealth results from the increase of share prices (Andres et al., 2009) as compared to the moment of the share purchase. The increase of the share price increases the value of stake held by the shareholder. The monetary effect is achieved at the moment of the sale of the shares – the difference between the purchase and sale price is the return on investment for the shareholder. The increase of the share price takes place when the company performs well and reports positive financial results. Under the circumstances of the constant value of the firm, shareholders may also enjoy the increase of the share price when the number of shares outstandingly drops. With the stock repurchase and the lower number of shares outstanding, the price per share naturally increases.

The second way to enjoy the return of investment by shareholders is the distribution of profits in the form of dividends. According to the agency theory, shareholders in public corporations are the residual claimants (Eisenhardt, 1989). They are not compensated in the fixed scheme but have the residual rights (Fama and Jensen, 1983a, 1983b). This means that shareholders are not rewarded by schemes adopted for employees or executives who receive monthly fixed remuneration paid on the basis of the contract regardless of the company performance. Employees are protected by law and have these payments guaranteed (which may be ceased in extreme situations of financial distress). Shareholders however are not subject to fixed payments; they enjoy the return of investment only if the company generates profits (Vermalen, 2009). In the case of financial loss or the need for reinvestment, shareholders do not receive any payment (Vogel, 2005; Dore, 2008). Since the payment to shareholders is dependent

on the financial performance of the company, they are called residual claimants and bear the risk.

The dividend payment depends on the financial performance of the company and its investment requirement as well as the quality and engagement of the executive team. Agency theory identifies that managers have the tendency to behave opportunistically and maximize their own wealth at the expense of shareholders (Jensen and Meckling, 1976). Hence, shareholders willing to enjoy positive return of their investment in a firm introduce control mechanisms to discipline managers (Eisenhardt, 1989) and a set of constraints that forms the *ex post* distribution of wealth (Zingales, 1997). In the language of the principal-agent framework, monitoring and control mechanisms (corporate governance) are set to ensure that investors receive the return on their investments and in a consequence are encouraged to provide more funds for companies in future (Shleifer & Vishny, 1997). As argued by Easterbrook (1984:652), “dividends exist *because* they influence the firms’ financing policies, *because* they dissipate cash and induce firms to float new securities.”

Measuring Dividend Payment

Dividend payment is an attribute of a company which adds to the assessment of its performance and indicates to what extent the company intends to share the profit with its shareholders. The dividend payment is measured by three indicators:

- Dividend yield defined as annual dividend paid per share divided by the price per share

$$\text{dividend yield} = \frac{\text{annual dividend paid per share}}{\text{price per share}}$$

- Dividend per share understood as the sum of dividend paid divided by shares outstanding

$$\text{dividend per share} = \frac{\text{sum of dividend paid}}{\text{shares outstanding}}$$

- Dividend payout ratio defined as annual dividend per share divided by earnings per share

$$\text{dividend payout ratio} = \frac{\text{annual dividend paid per share}}{\text{earnings per share}}$$

- Alternatively, dividend payout ratio is measured as sum dividend paid divided by net income

$$\text{dividend payout ratio} = \frac{\text{sum of dividend paid}}{\text{net income}}$$

Types of Dividend Payments

Companies may pay dividends in a number of forms. The existing literature distinguishes the following types of dividend (Bragg, 2017):

- Cash dividend – represents cash paid to shareholders who own company shares. It is expressed in the sum of money paid per each share owned. It is the most common type of dividend payment. Cash dividend is a form of investment income and is usually taxable to the recipient in the year it is paid. From the accounting perspective, dividends paid are not viewed as an expense but as the deduction of retained earnings. They are neither presented in the income statement nor shown in the balance sheet. Cash dividends may be paid as regular dividends (e.g., paid annually) or as special dividends which are less likely to be repeated and take place under certain special circumstances. For the cash dividend, three dates are essential: the date of declaration, the date of record, and the date of payment.
 - Date of declaration is the date of the decision by the board of directors to pay a certain dividend amount in cash to shareholders who own shares of the company on a specific date.
 - Date of record represents the date when dividends are assigned to the holders of the company's stock.
 - Date of payment is the date when the dividend payment is issued to shareholders.
- Stock dividend also known as script dividend is a dividend payment made in the form of additional shares not in the cash payout. This stock may be in the form of additional shares issued by the corporation or by an affiliated company (for instance, a subsidiary). Stock dividends are issued in the proportion to shares owned. The issuance of the additional stock up to 25% of the total number of previously outstanding shares is called as a stock dividend. The issuance of the stock exceeding 25% of the total number of previously outstanding shares is known as a stock split. Stock dividend also means that a given sum of money is transferred from retained earnings to the capital stock. The scrip dividend works as follows: A company may not have sufficient funds to issue dividends in the near future, so instead it issues a scrip dividend, which is essentially a promissory note that declares that the company will pay the dividends later since in the current situation it does not possess sufficient funds.
- Property dividend is the form of a non-monetary dividend to investors, not in the cash or stock payout. They are a rare type of dividends and are represented by the form of assets and securities from the issuing corporation or its affiliated company (for instance, a subsidiary). Property dividend may take forms of products and services.
- Liquidating dividend is the sum of funds which was originally provided by shareholders and is returned to them usually in the case of liquidation and closing down of the company.
- Interim dividend is a *dividend* paid to shareholders made before the annual shareholder meeting and final financial statements.
- Other dividends represent other types of payments to shareholders taking the form of structured finance.

Dividend Policy

The Lintner's Model

Dividend policy is a term which describes patterns and practice of the profit distribution by a firm to its shareholders (Baker et al., 2002; Allen & Michaely, 2003). It is studied in relation to a firm's financing and investment decisions. Dividend policy is the outcome of decisions undertaken by managers. The seminal work by Lintner (1956) offered first insights on dividend policy.

Lintner argues that companies follow dividend adjustment process by applying target dividend payout ratio. This means that companies set long-run target for dividends to earnings ratios according to the amount of positive net-present-value (NPV) projects they have available. Since earnings do not reveal stable and predictable increases, dividend policy is not adjusted according to their annual changes. The dividend policy is changed once managers view earnings increases as sustainable. According to Lintner, dividend policy has two parameters: the target payout ratio and the speed at which dividends adjust to the target.

The Irrelevance of Dividend Versus the Relevance of Dividend

The irrelevance of dividend is an approach offered in opposition to the view of the relevance of dividend and rests on the premise that “the value of a company is determined by its assets and the cash flows generated by those assets and not by the way firms distribute cash flows to shareholders” (Baker & Weigand, 2015:128).

According to the dividend irrelevance theory, investors are indifferent with respect to a firm’s dividend policy. Whenever they want to receive cash payment, they can sell a portion of their portfolio of shares (Andres et al., 2009). This means that investors do not expect a premium for any particular dividend policy. The irrelevance of dividend was proposed by Miller and Modigliani (1961) who argue that in perfect capital markets, the dividend policy does not impact firm share price. Dividend policy does not have any effect on firm value since it is determined by optimal investments.

Theories of Dividend Payout

The existing literature offers a number of explanations pointing at factors which determine the way and form of dividend payments, the frequency of the payments, and the size of the payments. A significant role is played by the corporate governance framework – investor protection and efficient court system are believed to increase the dividend payout by listed companies (La Porta et al., 2000). The

willingness of the firm to pay dividend, known as the firm propensity to pay, is believed to be the result of motivations for executives and market reactions.

Numerous studies attempt to explain dividend policy and the firm’s propensity to pay dividends. The factors which determine dividend payout include firm profitability and size, stability of earnings, rate of growth, free cash flow, life cycle, and investment opportunities as well as governing structure (Benjamin & Zain, 2015). Despite intensive analyses, there is not one universal and highly recognized conceptual framework which would explain why companies pay dividends (Baker & Weigand, 2015). Interestingly, studies indicate that factors which were believed to determine dividends policy prove to be insignificant with no impact of the frequency and the magnitude of the payout (Moortgat et al., 2017). Thus, authors often refer to the terms of “dividend puzzles” or “dividend enigma.” The existing literature offers a number of conceptual frameworks to explain dividend policy (Bancer et al., 2009; Baker & Weigand, 2015) including the following perspectives.

Bird in the Hand Versus Irrelevance

According to the bird-in-the-hand framework, investors prefer the certainty of dividend payments versus the possibility of higher capital gains in future (Baker & Weigand, 2015). Hence, companies which are willing to keep their share price high should pay dividends.

Tax Clienteles

According to tax clienteles, dividend policy is a product of tax law. Specifically, since investors maximize after tax income (Farrar and Selwyn 1967), companies pay dividends to meet the expectations of their heterogeneous groups known as clienteles (Masulis & Trueman, 1988; Allen et al., 2000). According to tax clientele, approach investors prefer that the company would retain the earnings if tax rates are high. In addition, due to tax law dividends are less valuable than capital gains; they are to some extent replaced by stock repurchases (Baker et al., 2002; Skinner, 2008; Baker, 2009). The replacement of

dividends by share buybacks is noted in many countries and is discussed in the next section.

Signaling Perspective

According to the signaling perspective, dividend policy is a way in which companies communicate information to shareholders (Denis & Osobov, 2008). Dividend policy is an instrument to send the message about the company quality to mitigate the information asymmetries (Frankfurter & Wood, 2002). The signaling perspective offers an explanation for the widely observed pattern of dividend payouts – dividend smoothing. Since investors negatively react to declines in payouts, managers adjust and smooth their dividends to meet the formulated targets (Leary & Michaely, 2011).

Agency Theory

Agency theory is used as a competitive perspective to explain dividend policy. This theory assumes the existence of the conflict of interest between (1) shareholders and debtholders (Fama & Jensen, 1983a, b) and (2) between shareholders and managers (Shleifer & Vishny, 1997; Easterbrook, 1984). Debt covenants are used to mitigate the conflict between shareholders and debtholders. The conflict between shareholders and managers and the risk of expropriation by managers are mitigated by the monitoring role of large owners, the presence of independent directors on board, and the incentive function of executive compensation.

The pattern of dividend payouts reflects the existing conflicts. According to agency theory, dividends are paid to mitigate the divergent interest of shareholders and managers. The payout reduces the cash flow at the managerial disposal (Frankfurter & Wood, 2002). Generated profits instead of being spent on transaction which does not increase shareholder value (excessive diversification, mergers and acquisitions, and prerequisite consumption) are distributed to shareholders (Jensen, 1986).

Developing this framework, Rozeff (1982) investigates the impact of transaction costs and agency costs relating to external financing. He suggests that the optimal dividend policy provides a balance between transaction costs and agency costs.

Catering Theory

Catering theory was developed by Baker and Wurgler (2004) who argue that investors divide companies into two groups: dividend payers or dividend nonpayers. According to catering theory, the decision to pay dividends is driven by investor demand. Specifically, “managers cater to investors by paying dividends when investors put a stock price premium on payers and not paying when investors prefer nonpayers” (Baker & Wurgler, 2004:1125). This means that companies adjust their dividend policies to investor demand – dividend payers reduce or cease dividends when demand is low, and payers are traded at a discount, while nonpayers initiate dividend payments when demand for dividends is high and when investors place a premium on dividend-paying stocks.

The main shortcoming of catering theory refers to the fact that it models decisions on dividend initiations and omissions but does not explain the changes in the size of dividends. This limitation was addressed by Li and Lie (2006) who further develop catering theory and indicate that the decision on dividend payment and the magnitude of the change are related to the premium that investors place on dividends (De Rooij & Renneboog, 2009).

Life Cycle Theory

An alternative explanation of dividend payout rests on the assumption that the dividend policy is a derivative of the firm's stage in its life cycle. According to this theory, in the early stages of its growth a company is unlikely to pay dividends. When its investment requirements are high, financing is based on equity and cash flow remains negative (Toms, 2014). The firm is about to initiate the dividend payouts “when its growth rate and profitability are expected to decline in the future” (Baker & Weigand, 2015:133). Fatemi and Bildik (2012) show that large firms with high profitability as well as firms with low growth opportunities have a greater propensity to pay dividends.

Behavioral Framework

Since the above presented frameworks failed to explain the dividend policy, the alternative

approach known as behavioral framework is proposed. According to the behavioral framework, investors prefer dividends for psychological reasons such as self-control (Shefrin and Statman (1984), choice under uncertainty (Kahneman & Tversky, 1979), mental accounting, hedonic editing, and regret. Other factors include demographic attributes of investors such as age, income, and retirement status. Depending on their demographic characteristic and psychological preferences, investors may prefer, for instance, high and stable dividend in order to lower the inconvenience and reduce the cost of creating the needed cash flows by liquidating share holdings (Shefrin & Statman, 1984; Baker et al., 2002).

Replacement by Stock Repurchase

In recent years, many articles on dividends have reported significant change of trends in the payouts by companies. The discussion was initiated with the paper by Fama and French (2001) who document the dramatic decrease of the proportion of firms that pay dividends in the period 1980s–1990s. This observation was later supported by empirical studies (De Angelo et al., 2004) that indicate the decline of the number and the proportion of firms which pay dividends as well as the drop of the funds distributed in the form of cash dividends to shareholders. Initially, this trend was noted in the United States. Later it was known as “disappearing dividends” or “shrinking dividends” (Siegel, 2002) and revealed also in other countries globally (Denis & Osobov, 2008; Fatemi & Bildik, 2012).

The trend of disappearing dividends is explained by several arguments:

- The changing breakdown of listed companies – the firm characteristics determines the frequency and magnitude of the payout. Thus, with the changes in the population of companies listed on the stock exchanges, the propensity to pay dividends may change as well (Fatemi & Bildik, 2012).
- Growth investment opportunities and requirements for capital – the expansion of companies

in sectors characterized with technological advancement and the importance of innovation increases the demand for capital and lowers the firms’ tendency to pay dividends (Fama & French, 2001).

- The impact of tax law and the widespread replacement of dividends by share repurchases noted in both the USA and Europe (Wood, 2001; De Angelo et al., 2004; Ferris et al., 2006; Shiller, 2014; Farre-Mensa et al., 2014).

Dividend and Sustainability

The link between dividend payout and sustainability is significantly unexplored, yet it constitutes a potentially interesting and relevant avenue for further research. The main assumption of the board that decides about the dividend payout to shareholders should not have a negative impact on the company and undermine its prospects for future development with regard to strategy, innovation as well as ESG performance.

Synonyms

[Domini Social Index 400](#); [MSCI KLD 400 Social Index](#)

Definition

The *Domini 400 Social Index* was initially founded by KLD's Amy Domini and is now known as the *MSCI KLD 400 Social Index*. It is a market cap-weighted stock index of 400 (out of 3000 of the largest in the United States) publicly traded firms which have met specific benchmarks of social and environmental distinction and

focuses on Socially Responsible Investing (SRI). The criteria for the index include high ratings based on Environmental, Social, and Governance (ESG) ratings. The companies must be headquartered in the United States and are primary listed on the NYSE or NASDAQ.

Companies included in this index have robust records of environmental and social excellence. In order to be included in this index, firms have to have made positive contributions to employee and human relations, product and environmental safety, and corporate governance. Those firms engaged in the business of alcohol, tobacco, civilian firearms, gambling, nuclear power, adult entertainment, genetically modified organisms (GMOs), and military weapons are routinely barred from being considered.

How the Social Index Works

The *MSCI KLD 400 Social Index* is independently maintained by *KLD Research & Analytics* and aspires to maintain similar sector weights as the MSCI USA Index. Firms are replaced from the index on a quarterly basis with those with higher ESG scores to maintain a fixed number of 400 securities based on one of three criteria: (a) if their ESG ratings decline below certain benchmarks, (b) if they are removed from the MSCI USA IMI index, or c) if they no longer pass exclusion criteria.

The index was established on May 1, 1990, as the *Domini 400 Social Index* and renamed as the *MSCI KLD 400 Social Index* in 2010. This was one of the first Socially Responsible Investing (SRI) indices, whose goal was to help socially conscious investors weigh social and environmental factors in their investment choices. This is a growing trend across many demographic and geographic corners of the world. Having a social conscience can be leveraged for competitive advantage for companies via their associations with shareholders.

The MSCI KLD 400 Social Index targets to own 90% large-cap stocks, 9% mid-cap, and 1% small-cap. As of July 2022, the indexes' largest holdings were Microsoft (MSFT), Facebook (FB), Google (GOOG), Proctor & Gamble (PG),

and Visa (V) – cumulatively they make up 21.5% of the index. Since the rechristening of the index in 2010 through January 2022, it has produced a return of 14.4% annualized.

In order to invest in the MSCI KLD 400 Social Index, one must buy the iShares MSCI KLD 400 Social ETF (DSI), an exchange-traded fund (ETF), formed in 2006. The assets under management (AUM) for the ETF is \$1.75 million, while the dividend yield is 1.5%. The shares are up 7.9% annualized since inception through January 2022. The ETF has the same top five holdings as the MSCI KLD Social Index.

Synonyms

[Sustainability Index](#)

Definition

The Dow Jones Sustainability Indices are stock indices that capture companies that are among the best in regard to sustainability. Listed companies are evaluated according to ecological, economic and social aspects (ESG criteria). The evaluations by S&P Global take data, evaluations of questionnaires, industry-specific aspects and other criteria into account, using standardized procedures. The Index Group enables companies that act sustainably to be compared with non-sustainable companies and they do create a reference in terms of sustainability.

Introduction

The Dow Jones Sustainability Indices is a group of equity indices that focus on sustainability. Its beginning was in 1999, started by the US publishing house Dow Jones & Company. Since then, a number of indices have been added. Today the overall group of these stock indices includes various global or regional as well as country-specific indices. The best-known Dow Jones Sustainability Index (DJSI) World is globally oriented. Further (regional) examples are DJSI Europe, DJSI North America or DJSI Emerging Markets.

The Dow Jones Sustainability Indices focus on sustainability. All parts of the index group have in common that they rely on the best companies when it comes to sustainability.

In terms of the indices, sustainability means focusing on economic, ecological and social criteria. In this respect, not only purely economic aspects (such as in the better-known “Dow Jones Index” - the US stock index created in 1884) are taken into account. The consideration also goes beyond purely ecological aspects. Rather, sustainability is made up of economic, ecological and social aspects in their entirety, i.e. environmental, social and management-specific aspects.

The indices take into account and record listed companies and evaluate them based on ESG criteria (environmental, social, governance) according to the best-in-class principle. The basis for evaluating companies in terms of sustainability is the S&P Global ESG Score of the company.

Evaluations by S&P Global Inc., a US financial services provider, form the basis for the assessment of companies in terms of sustainability and thus of those companies that are considered for the relevant indices. The company S&P Global took over this task in 2020 from the previously active company RobecoSAM, a Swiss-based investment company.

Methodology for Identifying the Most Sustainable Companies

S&P Global recently evaluated around 7500 companies that cover about 90% of global market capitalization (S&P Global, [2022a](#)).

Based on this total number of companies in order of their market capitalization, those companies are selected that are among the largest publicly traded companies in their respective industries. The selected companies are analyzed by using the so-called ESG criteria. These ESG criteria are checked and evaluated. In the determination, data, evaluations of questionnaires, industry-specific aspects and other criteria are taken into account using standardized procedures (Günther, [2018](#)). These can be aspects of corporate governance, risk management, or compliance issues. Questions of environmental reporting and CO2 compensation are also conceivable. Topics such as employee development, compensation

structures and corporate citizenship also play a role. So – to sum it up – on the one hand, there are general criteria such as management systems, human rights and leadership or aspects within the supply chain. On the other hand, there are still branch-specific aspects and peculiarities of individual branches of the economy. It is necessary to mention, that regarding to specific indices that there are exclusion criteria aiming to exclude some kind of companies such as firearms, alcohol and tobacco, or adult Entertainment.

The so-called S&P Global ESG Score is ultimately determined on the basis of this overall picture. This score can range from zero to 100 points. The higher the S&P Global ESG Score, the more sustainable the company is compared to the industry under review. This selection process is known as the “best-in-class” principle. In this respect, the number of points determined serves to select the most sustainable companies. At this point it must also be mentioned that a certain fluctuation in observance and compliance – depending on the criterion – is conceivable. In this respect, the evaluated aspects are subject to permanent monitoring and at the same time the medium-term performance of the company is decisive with regard to compliance with the criteria.

The Dow Jones Sustainability Indices are based on the evaluations by S&P Global. For example, the top 10% of companies are globally considered in the DJSI. The top 20% are considered for the regional indices, and the top 30% for country-specific indices (S&P Global, 2022b). In this respect, it is ensured that, in accordance with the “best-in-class” principle, companies are considered that implement the best services in terms of sustainability.

S&P Global analyzes are carried out once a year. At the same time, the companies are also subject to monitoring throughout the year. Changes during the year are also possible.

The Sustainability Yearbook

Regardless of the indices, the company S&P Global publishes its analyzes annually in the

Sustainability Yearbook (S&P Global, 2022c). It includes those companies that are in the top 15% of their industry and have an S&P Global ESG Score no more than 30% below the top company in the industry. A total of 716 companies out of about 7500 companies were included in the 2022 yearbook. An overview including the ranking of these companies can be found online on the website von S&P Global.(S&P Global, 2022d). With a view to recognizing the companies within the yearbook, the company S&P Global also publishes awards depending on the S&P Global ESG Score achieved: companies that achieve at least 60 points in their industry and are only 1% behind the top companies in the industry receive a “Gold” standard (“Gold Class Sustainability Award”). Companies with at least 57 points and a difference of 1–5% from the top companies in the industry receive a “Silver” standard (“Silver Class Sustainability Award”). Companies that achieve at least 54 points out of a range from 5–10% in comparison to the top companies in the industry receive a “Bronze” standard (“Bronze Class Sustainability Award”). Companies that are in the top 15% of an industry and can show an improvement in the S&P Global ESG Score of at least 5% and at the same time show the largest increase in the industry compared to the previous year receive the “Industry Mover Sustainability Award”. All other companies without an award are listed as members.

Critical Appraisal of the Dow Jones Sustainability Indexes

On a positive note, the introduction of the Dow Jones Sustainability Indices has put sustainability on the agenda. The Index Group also enables companies that act sustainably to be compared with non-sustainable companies or with companies that only focus on sub-areas of sustainability (which, for example, only take ecological aspects into account). In this respect, the Dow Jones Sustainability Indices create a reference in terms of sustainability.

For companies, the consideration is an award, seal of quality and honor at the same time,

especially since sustainability is one of the most important future topics not only from a regulatory point of view, but also due to market aspects. Sustainable companies strengthen their own competitiveness. In times of a difficult search for qualified employees, employees choose their employers as to whether they are sustainable. When buying products, consumers attach importance to how and under what conditions products are manufactured with a view to human rights or environmental aspects. And investors pay attention to compliance with ESG criteria when investing. The Index Group gives precisely these stakeholders the opportunity to invest in “good” companies. In addition to the image factor - which should not be confused with greenwashing – the consideration of the “best-in-class” principle can certainly also encourage more sustainability in the economy by means of the competitive spirit. If a company recognizes that another company is successful because it focuses on sustainability, then it is encouraged to do more with regard to its own sustainability. In relation to the political objectives, one should not forget the topic of sustainable finance. The European Union, for example, aims to not only make capital markets more sustainable, but also to use financial flows as a transmission channel of the credit and capital markets to bring the real economy toward sustainable economic activities.

The system of the Dow Jones Sustainability Indices admittance can certainly be criticized. For example, small companies are excluded due to the size of the capital market considered. How the criteria are weighted - for example between general and industry-specific aspects - when determining the S&P Global Score is undoubtedly a topic of discussion again and again.

Summary

The Dow Jones Sustainability Indices are stock indices that focus on sustainability. Every part of the index group rely on the best companies regarding the ESG criteria (economic, ecological, and social criteria). The evaluations by S&P Global take data, evaluations of questionnaires, industry-

specific aspects, and other criteria into account, using standardized procedures. The Index Group enables companies that act sustainably to be compared with non-sustainable companies and they do create a reference in terms of sustainability. For companies, it is an honor and a seal of quality to be considered because finally investors take a look where to invest their money.

Durable Survival of the Organization

Carmela Gulluscio
Unitelma Sapienza University of Rome, Rome,
Italy

Synonyms

[Economicità](#); [Enduring](#) outliving; [Long-lasting](#) survival

Definition

In the business administration literature, much attention has been paid to identifying the factors

allowing organizations to survive over time. Organizations are established with the need to satisfy human needs and with the prospect of lastingly surviving over time.

The concept of durable survival of the organization has been debated for several decades, but in recent years a lot has changed in the way of interpreting this phenomenon. Currently, the concept of durable survival of organizations is closely linked to the notions of sustainability and sustainable development. The latter was defined by Aras and Crowther (2009) as “a process which aims to fulfil human needs while also maintain the quality of the natural environment on an indefinite basis.”

In the traditional Italian business administration literature, the concept of lasting survival of business organizations is strongly linked to the concept of “economicità aziendale.” The latter is a positive property required to ensure that an “azienda” (roughly translatable as “organization”) can survive lasting over time. This contribution takes as a reference this concept, typical of a national business administration context since it can be a valid point of reference for reformulating the concept of lasting business survival in a contemporary and international point of view.

There are several interpretations and definitions of “economicità.” According to Sòstero (2003), these definitions can be located along an imaginary line with the following two extremes:

1. The “economicità” can be understood as the ability of the organization to *survive autonomously over time*, without the need for support from external agents.
2. It can be understood as *the success in achieving the purposes for which the organization was founded and for which it is kept alive*.

Among the many possible definitions falling within this imaginary line, we will refer to the following one, which is probably the most complete definition of “economicità.” According to Sòstero (2003), “the *economicità* is the organization’s ability to survive and to maximize the utility of its resources.” It depends both on the organization’s *performances* and on the achievement of *equilibrium conditions* allowing the organization

to lasting survive over time. The single parts of the definition will be in-depth examined in the “Performances and equilibrium conditions” section of this entry. Thereafter, the traditional Italian notion of “economicità” will be reformulated in the light of the “sustainability” concept which, in recent years, has been playing a crucial role in identifying the factors allowing organizations to survive over time and should be considered as a contemporary aspect of durability.

Introduction

The concepts presented in this entry are widely developed within traditional continental European accounting contexts and, in particular, in the Italian accounting and business administration literature. On the contrary, they are less popular in the Anglo-American context.

In the Italian accounting and business administration literature, the notion of durable survival of the “azienda” is very relevant. First of all, it is important to explain what the word “azienda” means. It is quite difficult to translate this concept into English. Many Italian accounting and business administration scholars tried to translate it into English to make clear to an international accounting and business administration community one of the most relevant concepts for the Italian accounting scholars. Some scholars tried to translate it with the word “concern” (AIDEA 1980), i.e., “the general category of administration unit (concern for-profit, non-profit and mixed ones), which tends to meet human needs through economic wealth” (Lipari 2012, p. 12).

In the Italian accounting and business administration literature, the distinction among the different types of “azienda” is very relevant and the conditions to achieve their durable survival vary according to their characteristics. Broadly speaking, a common distinction is made among:

(a) *Imprese* (roughly corresponding to “for-profit organizations”), i.e., organizations that allocate their goods and services to exchange on the market and whose main purpose is to achieve a profit.

(b) *Private not-for-profit organizations* (e.g., associations, foundations, and voluntary organizations). They mainly assign the goods and services produced to the consumption of their members (in the case of associations) or the supply to their community of reference (in the case of voluntary organizations and foundations) to achieve their statutory objectives.

(c) *Public not-for profit organizations* (e.g., public hospitals, schools, municipalities, etc.). They assign the goods and services produced to their community of reference to satisfy public needs.

The distinction among these three types of “azienda” is very important, since each pursues its specific institutional purposes (e.g., social, ethical, moral, economic, philanthropic, political, cultural, etc. aims) that can be very different, but all these organizations have in common the need to survive over time in a relatively autonomous way.

For reasons of simplicity, in the following, we will simply refer to the concept of “azienda” by translating it as “organization” (i.e., for-profit organization, not-for-profit organization, and mixed organization).

For a long time, the Italian accounting and business administration literature has identified two distinct objectives for the following types of “azienda”:

1. For for-profit organizations it was believed that the basic objective was the creation and distribution of a reasonable profit for the holders on own capital.
2. For not-for-profit organizations (both public and private) it was believed that the basic objective was the generic satisfaction of human needs, without pursuing profit goals.

However, the identification of two distinct purposes for for-profit and not-for-profit organizations has raised many doubts in doctrine, leading scholars to search for a universal goal, common to all types of organization, according to which each organization is established and maintained

(Gulluscio 2011, p. 23). Zappa (1956) has identified this objective in the survival of the organization, where the latter is interpreted as an economic institution that can last over time.

Only the organizations that manage to last over time can achieve their institutional goals on a stable basis. The durability of the organizations is independent of the permanence of people who have set up the organization itself and who operate in it at a certain time. The need to satisfy the organization's institutional goals does not only apply to the subjects who have established it and who operate in it at a certain time, but also to the people who will benefit from the organization's activity in the future.

The durable survival of the organization is closely connected to its *autonomy*. The latter should not be interpreted as total isolation from external influences, which are quite inevitable since the organization is an open social system. Autonomy means rather that the organization must be able to operate with the resources it manages to obtain, without the systematic recourse to third-party subsidies that condition its decision-making autonomy.

The organization's ability to persist over time and maintain a situation of relative autonomy, pursuing its institutional goals, depends on a set of *performances* and *equilibrium conditions* usually summarized in the concept of "economicità" and described in the next section of this entry.

Performances and Equilibrium Conditions

In this section, the definition proposed by Sòstero (2003) will be analyzed in detail. As already stated above, this is one of the most complete definitions of "economicità." According to it, "the *economicità* is the organization's ability to survive and to maximize the utility of its resources."

More in detail, it depends on two factors:

- (a) Performances
- (b) Equilibrium conditions

The *performances* are measured through the organization:

- Effectiveness
- Efficiency

The *equilibrium conditions* relate to these aspects:

- Economic
- Financial
- Monetary
- Owners' equity

As for the *performances* identified in the definition of "economicità," they include:

- *Effectiveness* (Gulluscio 2014a), commonly understood as the ability to achieve the desired purposes. In management and business administration, this term is commonly understood as "doing the right thing." With specific reference to the different types of "azienda" above-mentioned, effectiveness can be understood as their ability to satisfy their institutional goals. Effectiveness is therefore determined without taking into consideration the costs and is usually determined according to this formula:

$$\text{effectiveness} = \text{results/objectives}$$

There are relevant links between *effectiveness* and *efficiency* (i.e., the other performance mentioned in the definition of "economicità"). However, organizations can be effective without being efficient. This happens when the organization achieves specific results in a wasteful way.

- *Efficiency* (Gulluscio 2014b), which is usually defined in two different ways:
 - As the ability to minimize the resources used in comparison to the same result achieved
 - As the ability to maximize the result being equal the means employed

It is usually determined according to this formula:

efficiency = results achieved/resources used to achieve the results

As for the *equilibrium conditions* identified in the definition of “economicità,” they include:

- The *economic equilibrium*, i.e., the organization’s ability to operate in conditions allowing at least to restore the wealth consumed (Gulluscio 2014c). Depending on the type of organization considered, this equilibrium takes on different characteristics. In fact:
 - In *for-profit organizations*, this equilibrium is reached when revenues cover all costs and keep a reasonable margin for the return on equity.
 - In *not-for-profit organizations* (both public and private), this equilibrium is interpreted in a more restricted sense, i.e., as the ability to restore at least the wealth consumed during the organization’s operations. In fact, most public and private not-for-profit organizations sell the goods and services produced free of charge (or at lower prices than production costs). In these cases, it is important to assess whether the goods and services produced are useful to meet the institutional needs that the organization aims to satisfy. It is also important to compare the value of the utility that these goods and services have produced for users compared to the value of wealth consumed to produce them. In this way, it is possible to understand whether the organization can last durably over time, satisfying the needs of its community of reference, or if its activity is destined to cease because it cannot find forms of wealth restoration sufficient to cover the consumed resources.
- The *financial equilibrium* (Gulluscio 2014c), i.e., the adequate relationship between investments and financing.
- The *monetary equilibrium* (Gulluscio 2014c), which focuses on a short-term horizon, showing the organization’s ability to cover, at any time, payments through monetary assets.
- The *owners’ equity equilibrium* (Gulluscio 2014c), i.e., the organization’s ability to

accumulate and maintain a reasonable amount of assets compared to the funding needed to achieve the organization’s aims.

The equilibrium conditions above described are mutually connected and must be considered as minimum vital requirements for organizations. In other words, they represent necessary but not sufficient conditions to achieve the institutional aims of the organization and to ensure its durable survival over time.

Key Issues

One of the most complex factors to be considered to assess the durable survival of an organization is the economic equilibrium, i.e., *the organization’s ability to operate in conditions allowing at least to restore the wealth consumed*. Organizations failing to achieve this equilibrium can survive only through the systematic use of wealth restorations from third sources. As a consequence, these organizations lack their autonomy and are therefore destined to cease their activity.

To *restore at least the wealth consumed* means not just reintegrating exactly what was consumed, but also finding additional resources allowing the organization to grow and to adequately remunerate the stockholders (in for-profit organizations).

The economic equilibrium must be evaluated in a medium-long time horizon: Its lack in the short term does not necessarily compromise the organization’s durability. On the other hand, in the medium-long term, the organization’s autonomous survival skills are impaired if the economic equilibrium lacks.

The two main factors that must be considered in assessing the economic balance are the *finding of productive factors* and the *transfer of goods/services* produced. As for the finding of productive factors, in most cases, they are obtained against the payment of a price. However, there are some cases in which the production factors are obtained free of charge (e.g., work in voluntary organizations). In these cases, the purchase of inputs does not produce a direct impact on the economic equilibrium. As for the transfer of

goods/services produced, there is a significant difference between for-profit and not-for-profit organizations: The former usually sell their production at higher prices than production costs, while the latter (both public and private) often sell products/services for free or against prices below production costs. For the latter, the attainment of the economic equilibrium cannot disregard the contribution of non-operating items (e.g., transfers from other public entities, revenues different from exchange transactions, and revenues from non-operating items). In for-profit organizations, on the contrary, the economic equilibrium should primarily focus on operating items (i.e., operating revenues and expenses).

Future Directions

According to Freeman (1984), a stakeholder is anyone or an organization able to affect the fulfillment of organizational objectives through its action or who can be affected by the organization's actions. This concept is not stable over time; the identification of the organization's stakeholders is context and time-dependent. According to Mitchell et al. (1997), stakeholders are identified in those whose action matters to the organization. For these reasons, the concept of "stakeholders" is evolving over time. Several decades ago, organizational stakeholders were mainly identified in stockholders. Thereafter, other categories of subjects have gained importance in the communication processes of corporate information, e.g., customers, suppliers, the government, and lenders of credit capital. The recent increasing awareness of sustainable development goals (SDGs) leads to an increase in the number and type of subjects to whom it is considered important to report on the organizations' activity. The SDGs are 17 principles developed in 2015 by the United Nations as a worldwide call to action aimed at ending poverty, protecting planet earth, and ensuring that by 2030 people can enjoy peace and prosperity. In this context, everyone can be considered as a stakeholder. This point of view is coherent with Freeman (1984),

who argues that organizations are responsible to the whole society in which they operate.

The stakeholders to whom it is necessary to report the organization's work are increasingly broad categories of subjects. It follows that today more than ever, broader and more varied categories of stakeholders are considered important for the organizations' lasting survival (i.e., for its durability). The concept of "economicità" should therefore be revisited and expanded. From a viewpoint of sustainability and sustainable development, the aforementioned equilibrium conditions represent only one aspect to be met to guarantee the lasting survival of the organization. The four *equilibrium conditions* cited above (i.e., economic, financial, monetary, and owners' equity equilibria) simply represent an *internal* and *short-term*-oriented dimension for the organization. According to Aras and Crowther (2009), this dimension is called "finance," and consists of maintaining economic (and of course financial, monetary, and owners' equity) equilibria. It is one of the four dimensions of Aras and Crowther's (2009) model of sustainable development, displayed in Fig. 1. According to Aras and Crowther (2009), this dimension is the main goal of the organization. To survive over time, organizations must stably reach other three conditions, namely:

- Societal influence (i.e., ensuring social justice). This condition is reached through poverty reduction, protection of human rights, universal access to education, peace promotion, etc.
- Environmental impact (i.e., safeguarding the environment). This is an essential condition for preserving the availability of production factors to future generations.
- Organizational culture (i.e., developing spiritual and cultural values). This dimension is reached when societal and corporate values align in the individual.

The three conditions just mentioned are considered in the contemporary interpretation of the "simultaneous maximums" concept, to which we refer (cross-reference here to ► ["Theory of](#)

Simultaneous Maximums” to ► “Business Case of CSR” entry).

The concept of “*economicità*” presented in this entry is very broad: It includes the analysis of various dimensions necessary to achieve the lasting survival of different types of organizations (public, private, for-profit, and not-for-profit). In the international (and especially Anglo-American) literature, these same concepts are addressed, but normally this happens with a focus on single aspects considered one at a time and not through a single and comprehensive concept like the one examined here. International literature focuses, for example, on the concepts of effectiveness, efficiency and the various financial statement equilibria in different types of organizations, but it is not usual to address these issues by condensing them into a single concept applicable to all types of organization. Furthermore, few are the contributions focusing on the need to combine the internal and short-term-oriented dimensions (above named “finance”) with the other three dimensions presented above.

The traditional Italian concept of “*economicità*” can be reformulated in the light of the “sustainability” concept. The *economicità* can be therefore understood as the organization’s ability to lasting survive and to maximize the utility of its resources. It depends on various conditions having internal and external focus, and on the short-term- and long-term-oriented aspects, namely:

1. The organization’s performances
2. The achievement of equilibrium conditions allowing the organization to lasting survive over time
3. Ensuring social justice
4. Preserving the environment
5. Developing spiritual and cultural values

Figure 2 shows that three dimensions proposed by Aras and Crowther (2009) in their model of sustainable development (i.e., societal influence, environmental impact, and organizational culture) maintain the position they originally had in this model. Aras and Crowther’s dimension “finance” was divided into two parts:

Durable Survival of the Organization, Fig. 1 Aras and Crowther’s (2009) model of sustainable development

Durable Survival of the Organization, Fig. 2 Reformulation of the “economicità” concept in the light of sustainability (our adaptation from Aras and Crowther 2009)

- A short-term-oriented equilibrium condition, i.e., monetary equilibrium
- A long-term-oriented equilibrium condition, including economic, financial, and owners’ equity equilibria

As explained in the sections devoted to “Performances and equilibrium conditions,” only monetary equilibrium is short-term oriented, while the other three equilibria are medium-/long-term oriented.

Moreover, the “performances” included in the concept of “economicità” are placed within Aras and Crowther’s (2009) model of sustainable development according to their focus. Efficiency can, therefore, be considered as an internal performance dimension short-term oriented. Effectiveness, on the contrary, can be considered as an external performance dimension, since it relates to “doing

the right thing” for the organization and its stakeholders.

The reformulation of the “economicità” concept in the light of sustainability adapts an old concept of the Italian business administration theory to a more contemporary logic in which the survival of companies over time is conditioned to the achievement of sustainable development not only in the classic economic/financial/monetary/owners’ equity dimension but also in the other dimensions impacting on stakeholders and global society.

The development of an international debate on such a vast concept is indeed desirable since it can represent a future point of connection for accounting studies relating to an important dimension of corporate sustainability: Namely the financial and non-financial dimensions of sustainability, arising from financial statements and non-financial reporting data.

Summary

The old Italian business administration concept of “long lasting survival” of organizations has relevant links with the more modern and international notion of sustainability. The former has strong links with another classic notion of the Italian business administration tradition named “economicità.” The latter implies not only the achievement of economic and financial equilibria but also of social and environmental sustainability. The concept of “economicità” can be placed along an imaginary line with the following two extremes:

(a) A simple interpretation, according to which it is an organizational equilibrium. It is understood as the ability of the entity to survive autonomously over time without support from external parties.

(b) A more complex interpretation, i.e., the success of the entity in the achievement of the purpose for which it was founded and kept alive.

Broadening the field of observation from the concept of “economicità” to those of sustainability, an organization will have durable survival when it is able to achieve the objectives for which it was established and kept alive, in compliance not only with the abovementioned economic and financial equilibria (typical dimensions in financial reports) but also with the social and environmental objectives of its various stakeholders. In order to survive over time, contemporary organizations cannot limit themselves to producing products and services capable of satisfying the needs of their customers and users, and it is not even enough that the satisfaction of these needs takes place in conditions of economic and financial equilibria. It is necessary that all corporate stakeholder are adequately satisfied, even those who express expectations in the social and environmental sphere.

Synonyms

[Productive efficiency](#)

Definition

Dynamic efficiency is a core topic in economic growth analysis. Dynamic efficiency is concerned with the productive efficiency of a firm over a period of time. Therefore, dynamic efficiency is concerned with the optimum pace of innovation and investment to enhance manufacturing procedures that assist to decrease the average price curves in the long run. Investment in new machinery and technology, for instance, may allow labor productivity to rise. Implementing better working methods and better management of human capital may also require dynamic efficiency. For instance, better union connections that assist implement new work methods. A trade-off includes dynamic effectiveness. In the brief term, investing in better technology may entail greater expenses. But the company may not be able to enhance over time without this investment and innovation (Economics Help 2019).

The economy is said to be dynamically inefficient in situations where the population growth rate exceeds the stable state marginal product of capital, or where the economy consistently invests more than it earns in profit (Abel et al. 1986).

In 1998, a significant handbook on institutional financial evaluation was released by Wolfgang Kasper and Manfred E. Streit. The writers describe dynamic efficiency in this book as “an intrinsic quality for adapting, responding to, or developing fresh understanding.”

The Concept of Dynamic Efficiency

Productivity is, broadly speaking, a measure of how effectively an economy uses resources to generate economic output. Increasing the effectiveness of companies, public sector bodies, and nonprofit organizations can increase productivity. Economists generally differentiate between three kinds of efficiency: allocative efficiency, productive efficiency, and dynamic efficiency. The first two of these are static ideas of how much can be generated at a certain stage in time from a specified resource inventory. The third is a vibrant idea,

concerned with pushing out the boundaries of production possibilities and offering the community access over time to more and better products and services (Dolamare 2014):

- Allocative efficiency – ensures the allocation of resources between alternative uses in a manner that maximizes the well-being of the society.
- Productive effectiveness – defines the condition with the smallest possible average price of producing production. This happens when an organization, a sector, or an economy as a whole operates on its potential manufacturing border (i.e., generating the highest output from a set of inputs).
- Dynamic efficiency – means enhancing the effectiveness of allocation and production over time. This can involve developing fresh or better products and discovering better methods to produce goods and services. Learning, investment, and innovation are important components of dynamic efficiency.

Factors affecting dynamic efficiency:

- Investment – investing in fresh technology and enhancing capital can result in reduced expenses in future state of technology. Rapid technology development can allow companies to generate more for reduced expenses.
- Workers’ and managers’ motivation – do executives have incentives to take risks and innovate or is the company’s structure set up to promote stagnant growth?
- Finance access – a company that does not have access to finance will strive to invest in fresh capital that will allow reduced expenses.

Examples of dynamic efficiency: In 1923, one of the most efficient companies in the globe was Henry Ford’s automobile factory – making the most efficient use of assembly lines. Ford was the most effective car manufacturer throughout the 1920s and 1930s. However, it began to lose its competitive advantage by the 1950s and 1960s as Japanese vehicle companies innovated and enhanced car-building quality (Economics Help 2019).

Dolan and Lindsay (1988) provide a much more specific assessment of dynamic efficiency, particularly when it comes to distinguishing between static effectiveness and dynamic efficiency, which they describe as “a measure of the speed at which the frontier of manufacturing possibility changes over time.” In comparison, static effectiveness is described as “a measure of how near an economy reaches its manufacturing potential frontier.” In addition, Dolan and Lindsay refer to the pioneering contributions of Schumpeter in the field of dynamic efficiency and consider innovation and technological discoveries to be the primary forces behind it, although they do not neglect to mention the creative strength of entrepreneurship.

Dynamic efficiency requires resource allocation that ensures the financing of the optimal number of high-technology firms. For this aim, dynamic efficiency with interacting economic agents is needed (Schertler 2003).

Dynamic Efficiency Criterion

The economy is said to be dynamically inefficient in situations where the population growth rate exceeds the stable state marginal product of capital, or where the economy consistently invests more than it earns in profit. Tobin (1965) and Solow (1970) base their judgment that the economy is dynamically efficient based on estimates of the marginal efficiency of capital obtained from observed accounting profit levels. An alternative approach explains the dynamic efficiency in the light of the monetary variables. Therefore, in a competitive economy, the question of dynamic efficiency can be solved by comparing the amount of investment with the cash flows produced by manufacturing after salaries are paid (Abel et al. 1986).

Summary

Dynamic efficiency is a core topic in economic growth analysis. It is concerned with the productive efficiency of a firm over a period of time and to do that deals with innovation and enhancing. It requires resource allocation, and firms have criteria to be dynamic efficient.

Definition/Description

The United Nations Conference on Environment and Development (UNCED), also known as “Earth Summit,” was held at Rio de Janeiro,

Brazil, from 3 to 14 June 1992 (UN [2019](#)). The Conference was the biggest summit that focused on the impact that socioeconomic activities had on the environment. It addressed crucial issues of climate change caused by human activity in an unprecedentedly global manner by bringing together leaders, policymakers, diplomats, scientists, media, and nongovernmental organization (NGO) representatives of 176 states and territories (UN [1992a](#)). Several United Nations (UN) organizations and specialized agencies, 35 intergovernmental organizations, and some 1500 nongovernmental organizations (NGOs) were also represented (UN [1992a](#)).

UNCED coincided with the World Environment Day (5 June), and the twentieth anniversary of the opening of the United Nations Conference on the Human Environment, held in Stockholm in 1972 (UN [1992a](#)).

A number of documents emerged from the Conference. On 14 June, it adopted the Rio Declaration on Environment and Development, and Agenda 21 – a comprehensive action plan for the sustainable development of the planet into the XXI century. A statement of principles for a global management, conservation, and sustainable development of forests was adopted. The United Nations Framework Convention on Climate Change and the Convention on Biological Diversity were opened for signature at UNCED, and they were signed by 154 States and 156 States,

respectively, and by one regional economic integration organization (UN 1992a).

Introduction

With the Cold War behind the world's back, the international community had recognized that a new form of communication needed to be set when decision-making about global problems was in order. At the time, climate change was not as widely considered a global threat of highest priority, but there were more and more evidences that proved the importance and urgency of the issue. Preparations of key issues and core documents began in 1989 after General Assembly resolution 44/228 of 22 December 1989 was adopted by the nations of the world that called for the United Nations Conference on Environment and Development, acknowledging the need for an integrated approach to environment and development questions (UN 1993), the Rio Conference was an important summit both because of the issues it addresses, and because of the large number of delegates. It included not only representatives of governments, but the nongovernment sector as well; it was covered by media from all around the world. The UNCED was the formal starting point of the sustainable development thread of work of the United Nations.

Subsequent events that followed the Rio Conference of 1992 were the signing of the Kyoto Protocol, the World Summit on Sustainable Development in 2002 (Rio + 10), the Rio + 20 Conference. The Conference of Parties (COP) to the United Nation Framework Convention on Climate Change (UNFCCC) became regular events since the adoption of the Convention. The most visible summit after the Rio Conference in 1992 is considered to be the Twenty-First Conference of Parties (COP21), also known as the 2015 United Nations Climate Change Conference, which led to the adoption of the Paris Agreement in 2015, considered by some to be a shift towards a soft global governance for climate change (Leal-Arcas and Carafa 2014).

The first Earth Summit was essentially the pioneer of the truly global environment and development dialog. It was characterized by the massive representation of the event in media and unprecedented number of participants that gathered for discussion panels and decision-making (UN 1993), with more than 10,000 journalists covering the Summit, and still is considered one of the key events in United Nations history in paving the way for the formation of the global sustainable development goals.

The Role of the Rio Conference in Sustainable Development

The Rio Conference of 1992 was the first and one of most important of many events that shape the third period of the sustainable development concept evolution (post-Brundtland report period).

It is from the Rio Conference and the documents that were adopted at the conference that three key elements of the contemporary sustainable development concept were identified: 1) the concept of economic development that is in line with existing ecological constraints; 2) the concept of needs in terms of resource redistribution to ensure the quality of life for all; and 3) the concept of future generations and responsibility to ensure long-term usage of resources, and guarantee the possibility for future generations to be able to benefit from a good quality of the environment (Klarin 2018).

Documents Adopted at the Rio Conference

As a result from the Earth Summit some very important documents – both political and legal ones – were adopted:

1. *Rio Declaration on Environment and Development*

The Rio Declaration on Environment and Development is one of the two main political

documents adopted at the Rio Earth Summit. It contains 27 principles of sustainable development on the rights and responsibilities of the United Nations. These principles also form the basis for future policy and decision-making, aiming at achieving balance between socioeconomic development and protecting the environment (UN 1993).

2. Agenda 21

The Summit also adopted the Agenda 21 – a thorough and broad-ranging program of actions to reach global sustainable development in the twenty-first century, which recommended a broad range of actions – from new ways to educate, to new ways to manage natural resources, and new ways to participate in designing a sustainable economy (UN 1993). Agenda 21 has been considered one of the most ambitious UN plans.

3. *Nonlegally binding authoritative statement of principles for a global consensus on the management, conservation, and sustainable development of all types of forests* – the document concerns environmental and developmental issues of forests, with the main goal set in them to maintaining and increasing forest cover and productivity in ecologically and economically sound ways. The principles affirm sovereign rights of states to utilize and manage forests in a consistent with sustainable development way. The principles focus on the development of inclusive, economically and socially, sustainable ways of governing forests. A call for strengthening the institutional mechanisms for sustainable forest management on the local, regional, and international level is made (UN 1992b).

4. United Nation Framework Convention on Climate Change (UNFCCC).

The UNFCCC entered into force on 21 March 1994 (UN 2020). Today, it has near-universal

membership. The 197 countries that have ratified the Convention are called Parties to the Convention (UN 2020).

The UNFCCC is a key legally binding convention that up to the Paris Agreement provided the main legal framework for international cooperation on combating climate change and limiting the effects of human activities that harm the environment.

The UNFCCC bound member states to act in the interests of human safety even in the face of scientific uncertainty. It set a goal to stabilize greenhouse gas concentrations. It states that such a level of greenhouse gas emissions should be achieved that would be sufficiently low to allow ecosystems adapt naturally to climate change (Kameyama and Kubota 2010). A system of reporting and monitoring greenhouse gas emissions was developed, and further policies and measures were introduced through the Kyoto Protocol and other latter documents attached to the Convention.

The Convention recognized the historical path dependence of the impact of human activity on the environment. For this reason the Convention put the major responsibility on developed countries (the so-called Annex 1 countries) to lead the way to a more environmentally responsible economic growth.

Industrialized nations agreed under the Convention to support climate change activities in developing countries. A system of grants and loans that has been set up is managed by the Global Environment Facility (GEF) (GEF 2018).

5. Convention on Biological Diversity – the objectives of the Convention are the conservation of biological diversity, the sustainable use of its components, and the fair and equitable sharing of the benefits arising out of the utilization of genetic resources, including by appropriate access to genetic resources and by appropriate transfer of relevant technologies, taking into account all rights over those resources and to technologies, and by appropriate funding (UN 1992c). The Convention promotes international economic and social

cooperation and stresses on the significance of changing production and consumption patterns in both national and international markets, as well as the importance of local and indigenous communities, as well as the inclusion of women in using and conserving resources (Kimball 1997).

6. United Nations Convention to Combat Desertification (UNCCD) – As one of the outcomes of the UNCED, Resolution 47/188 was adopted with the proposal for developing the draft of the UNCCD (Longjun 2011). The process that started at the Rio Conference ended with the endorsement of the UNCCD in 1994. The Convention came into force in 1996 with 193 parties that adopted the document (Longjun 2011). The objective of this Convention is to combat desertification and mitigate the effects of drought in countries experiencing these challenges. It focuses particularly in Africa. The Convention promotes action at all institutional levels and calls for the pursuit of sustainable development in these regions through long-term strategies and action, including through international cooperation and partnership arrangements (UN 1994a, b).

Long-Term Impact of the UNCED and Follow-Up Processes

The first Rio Conference initiated a multi-stakeholder dialog about sustainable development within the framework of the UN. Follow-up Summits to the UNCED were the Rio + 5, Rio + 10 (c. World Summit for Sustainable Development), and Rio + 20 Conferences.

Another major follow-up of the UNCED was the initiated Conference of Parties (COP) process to the UNFCCC. The implementation of the convention lead to the adoption of the Kyoto Protocol in 1997, and the quota system for national greenhouse gas emissions that is one of the most effective international measures for global warming combating (Roberts 2015).

Sustainable development which was coined as a term within the framework of UNCED became a major global goal. Both countries and

international organizations became highly engaged in the process of developing sustainable economies and societies (Klarin 2018).

Criticism of the Rio Conference

Despite the Rio Summit being the largest conference of this kind, it still faced some criticism. There have been opinions that UNCED did not produce enough binding principles of international environmental law that would be sufficient to protect the environment (Palmer 1992). A severe criticism is that the meeting failed in changing the essential characteristic of international environmental law, namely that it lacks central authority for creation and enforcement (Palmer 1992).

Summary

The United Nations play a vital role in the advancing of sustainable development on both a theoretical and practical level. The United Nations Conference on Environment and Development turned out to be a key event in both aspects. It provided the contemporary foundations of policymaking and coordination in the sphere of climate protection and sustainable development promotion.

The UNCED became the foundation for the process of evolution and promotion of sustainable development, and its impact is still sensed today in all follow-up processes that are taking place on both international and national levels. For that reason it has been considered one of the most important events in worldwide environmental action and sustainable development promotion.

Ecocultural Tourism

Gonçalo Poeta Fernandes
Polytechnic Institute of Guarda, CITUR,
CICS-NOVA & UDI/IPG, Guarda, Portugal

Synonyms

Eco-cultural tourism; Ecocultural tourism experience; The ecocultural tourism

Definition

It's necessary to recognize that tourism and leisure visitors often take part in mixed portfolios of experiential activities that mix nature and culture, and these are not easily or exclusively classified.

Ecocultural tourism is considered a “concept in which ecological and cultural aspects of a landscape are combined to create a site for tourists” (Wallace and Russell 2004: 235). It is understood as a holistic approach in which communities articulate the cultural and ecological resources in the tourism fitment and increase notoriety associated with the values held by the territory, combining the patrimonial dimension, culture, and identity with the didactic dimension and citizen science. It considers sustainability and community participation crucial elements for the development of this form of tourism, regarding at the same time a necessary active involvement of local government in the development of the capacity for its realization.

At present the tourist experience seeks to achieve the different tourism resources of the destination/region, natural and cultural, trying to understand its origins and established relationships with communities. In this way, there is a value articulation in a composite product, reaching its origins, evolutions, and relations built, with its consequent materialization in the territory. The conceptual dimension of ecocultural tourism is based on the incorporation of knowledge and culture into the natural resources and the development services, perceiving the connections, the materializations, and the forms of appropriation by the local communities of the natural elements. In this context landscapes are the main arguments of ecoculture tourism, being interpreted at different geographical scales (and levels of detail) and reaching, in a combined way, the individual to the collective, allowing complete knowledge, that is, and figuratively, from the stone to the monument or the climate to community practices.

Introduction

Ecocultural tourism aims to protect natural and cultural values and pursues Sustainable Development Goals (SDGs) by supporting the conservation of natural resources and biological and landscape diversity and promoting geo-ecological protection for the well-being of local communities and their development. Ecocultural tourism is thus a result of complementarity between the geography of the place, the heritage, the ways of life, and the economic and sociocultural organization of the community. In this approach the community assumes a relevant role in the relationship with tourists and the territory, promoting the compression of the connections between traditions and socioeconomic and cultural practices with the geographical space, promoting value and experiences.

Significance and Territorial Impact of Ecocultural Tourism

Ecocultural tourism defines “destinations where both cultural and natural endowments are the prime attractions and thereby considered to be a potential strategy to support conservation of natural habitats along with economic sustainability” (Cajee 2014: 9). Ecocultural tourism values cultural identities, geodiversity, and ways of life in an interactive relationship that allows local people to build a sustainable future based on their natural and sociocultural resources, which appeal to their interpretation and sensory experience. It requires a process of collective responsibilities and operational empowerment, to achieve social and cultural empowerment, for which government entities should be articulators, inspirers, and financers of actions, seeking successful tourism development, particularly in peripheral areas of great socioeconomic weakness. The participation and involvement of the community are determinants for ecocultural tourism, as it is a key factor for these destinations and the legitimization of this product. The community is part of the cultural asset of this product, which is materialized in the

natural specificities and in the relationships promoted over time. The understanding of local ecocultural realities, the development of preservation processes, and heritage valuation, in connection with local geographic factors, structure this tourism.

Ecocultural tourism is recognized as sustainable and consubstantiates the integration of natural and cultural values, supporting geo-conservation and biodiversity. Simultaneously preserves the “identity of local communities and improves their socio-economic status, enhancing new development projects using local cultures or resources” (Gang 2011: 17).

Ecotourism has an unsustainable dimension (from the point of view of the relationship with the community and its sociocultural practices) and they consider that there should be an approach of greater inclusion and protection, promoting and strengthening the ecological and cultural binomial as a determinant for a deeper knowledge of territorial realities, their specificities, and interrelations developed over time.

Today, we seek to strengthen the ecocultural offer, proactively with the participation of the community in valuing the identities and ways of life, the traditions, and their affectations with the geographic dimension of the destination (Rotherham 2013). In this context, experiences and traditions valorization are preserved, landscapes are conserved, and patrimony is defended (natural and cultural), complementing the cultural aspect with environmental education.

The term ecotourism has been adopted widely as a generic description of tourism with a primary aim to interact with nature and at the same time to involve minimal negative impacts. Furthermore, there is an assumption that local communities will benefit from such tourism and that in the process of these interactions and activities, nature will be conserved (Roe et al. 1997).

“The concept of ecocultural tourism which is, therefore, a subset of ecotourism is framed by integrating ecotourism as a sustainable form of natural resource-based tourism and its prevalence culture” (Cajee 2014: 2). We are in an integrated

approach to tourism where ecological and cultural aspects of a landscape/territory are combined and provided an interpretive and experiential “scenario” for tourists. The geological and ecological elements and the cultural references combine to promote a broader and more advanced experience of the tourist destination, promoting the knowledge of established relations. The development of guides, roadmaps, and other information supports consolidating the experience and enriching the knowledge in turn of these resources.

The interplay between the human culture and the environment that it exists in, including but not limited to, the challenges of regaining and retaining this connection through means such as sustainable development. It corresponds to a way of authentically experiencing the local cultural and ecological identities (Tiberghien et al. 2017; Dowling 2010). It is an alternative to mass tourism, and with a close relationship with the community in a constructive way and preserving values and ways of life, particularly in rural and less developed areas, like mountains, low-density areas, and historical villages, many of these spaces are already integrated into natural parks, geoparks, and nature reserves among other classifications.

This leads us to consider an “integrated or hybrid concept of eco-cultural tourism based on stakeholders with broadly based interests and resources that combine ecological, heritage and cultural assets” (Rotherham 2013: 49). Given the growing interest of tourists in a wider knowledge of the realities of visits, knowing nature and its patrimony elements, besides the visual or aesthetic dimension, the incorporation of knowledge (science), environmental education, and appreciation of the local culture. At the same time, the relationship between the forms of appropriation and uses, cultural traditions, and ways of life takes on meaning in the tourist experience, which implies their preservation/conservation (Fig. 1). Ecocultural tourism is thus a result of complementarity between the geography of the place, the heritage, the ways of life, and the economic and sociocultural organization of the community (Wallace and

Ecocultural Tourism,

Fig. 1 Structuring elements of ecocultural tourism and its impacts on territorial valuation and sustainability

Russell 2004). These aspects generate differentiations, materialized in the landscapes, with different intensities of transformation, generating identity and even territorial mark, valuing touristically the territory, and demanding a growing effort in its promotion and the tourist reception capacities.

For an emerging tourism destination, the assessment and evaluation of “natural capital,” “heritage capital,” and “cultural capital” provides an overarching vision to better inform any models of potential development and possible conflicts. “The ecosystem diversity refers to the variety of habitats, biological communities and ecological processes within the ecosystems. It also involves the diversity of people who live there” (Poyya Moli 2008: 134).

Ecotourism is defined by The International Ecotourism Society as “responsible travel to natural areas that conserves the environment and improves the well-being of local people” (Wood 2002). This promotes an experience that inspires tourists to analyze, interpret, and understand the ecological system of the communities and their cultural identities in an integrated way and with preservation concerns (Fennell 1999; Jopp et al. 2021). Given this framework and the growing pretension of an integrated observation and interpretation of the natural conditions of the environment, in strict

interpellation with the human activities and forms of appropriation of the territory, that is between nature and sociocultural backgrounds, the term ecocultural best represents this tourist demand. It promotes, in a sustainable way, local development, the protection of natural and cultural resources, creating value and new opportunities for the territory, and articulating socioeconomic interests with preservation responsibilities.

In this concept, which adds more and more tourist practices, the community is fundamental, in the knowledge and dissemination of its tourist resources, in the maintenance of the ways of life and the traditions, incorporating continuity (preservation), differentiation, and economic value. In this context ecocultural tourism promote alternative and sustainable services while safeguarding the values of the ecosystem and social equity.

Summary

Ecocultural tourism is a result of complementarity between the geography of the place, the heritage, the ways of life, and the economic and sociocultural organization of the community. The local residents and governance are a fundamental role in the knowledge and dissemination of its tourist

resources, in the maintenance of the ways of life and the traditions, incorporating continuity, preservation, promoting territorial value, sustainability, and experiences based on cultural and natural identities and heritages.

Definition

The term eco-efficiency originates from the fusion of two words, the noun “efficiency” and the adjective “ecological.” It was created in 1992 by the World Business Council for Sustainable Development and quoted in the publication “Changing Course” (Schmidheiny and Timberlake 1992).

It refers to the managerial attitude that aims at decreasing ecological damage while increasing the efficiency of the production processes; minimizing the use of energy, material, and water; recycling more by-products; and eliminating hazardous emissions or wastes.

The notion was publicized by the BCSD (Business Council for Sustainable Development) in 1992 during the World Conference on Environment and Development in Brazil and consists of offering goods and services at a competitive price, satisfying human urgencies and ensuring the quality of life while reducing

ecological impacts and resource exploitation throughout the life cycle to a degree at least in line with the carrying capacity of the Earth (WBCSD 2000).

Historical Development of the Concept

The impact of anthropic activities on the environment was first studied, during the 1970s, by Ehrlich and Holdren (1971), considered the founders of the ecological economics research field, which formalized the following equation:

$$Impact = f(Population, Affluence, Technology)$$

Before the abovementioned publication “Changing Course,” the notion of eco-efficiency was developed by McIntyre and Thornton (1978), but the term was formally created and explicated by Schmidheiny and Timberlake (1992). He asked for a change in the perception as a key part of the solution for stopping environmental degradation and achieving global sustainable development (Ehrenfeld 2005; WBCSD 2000).

Thanks to some forward-looking managers and thinkers, eco-efficiency evolved from an idea to a concrete, experimental, and applicable theory, culminating in the publication of the Environmental Performance and Shareholder Value report (Blumberg et al. 1997).

Von Weiszäcker et al. (1998), in the book titled *Factor Four*, reformulated the concept of efficiency and proposed a meaning of the term eco-efficiency. In their publication, efficiency is intended as something which enables the well-being of humanity to be separated from the consumption of resources. According to the authors, improving and calibrating efficiency, through a series of techniques and methodologies already available, it is possible to quickly reach a more rational use of resources, achieving environmental, social, and economic benefits.

Starting from the concept of efficiency, which, according to the ISO 9241 standard, indicates

the accuracy and completeness of the objectives achieved in relation to the resources spent, the adjective ecological characterizes the abovementioned objectives, ascribing them to the field of complex interactions and equilibria between living organisms and the surrounding environmental conditions, generated by natural abiotic and biotic components and by factors present in that particular environment.

The concept of eco-efficiency therefore indicates the ability of an organization to achieve the goals of construction, production, and supply of commodities and services using fewer and fewer resources and generating less and less waste and pollution. To understand the degree of eco-efficiency of a given eco-system, the consideration of three factors is relevant:

- The material, energy, and information flow that is determined in that context
- The interdependence of the organisms that live in that context
- The effectiveness of the material and immaterial flows taking place between the various levels of the ecosystem organization

According to the WBCSD, the strategies to achieve eco-efficiency consist in, on the one hand, reducing the dispersion of toxic materials and waste in general and, on the other hand, increasing the recyclability of materials and waste, the use of renewable resources, and the duration of components (WBCSD 2000; Lovins 2012).

Eco-efficiency Assessment

Considering the current economic turbulences, the environmental challenges and pressures for a more sustainable world, the new international standard UNI EN ISO 14045 named “Environmental management – Eco-efficiency assessment of product systems – Principles, requirements and guidelines” holds enormous and global potential.

The rule describes the principles, requirements, and guidelines for the eco-efficiency evaluation of a product system. The key objectives are:

- To establish a clear terminology and a common methodological framework for the evaluation of eco-efficiency
- To provide precise guidelines on the interpretation of the results of these assessments
- To encourage transparent and precise communication of the results

Eco-efficiency is a factor of sustainability that links the environmental performance of a product's life cycle to its value. In a world characterized by some full developing countries, the eco-efficiency assessment represents a management tool necessary to decrease the overall environmental impact.

Eco-efficiency is increasingly becoming an essential requisite for the success of companies. By applying ISO 14045, the user will be able to simultaneously manage the characteristics of environmental, commercial, and economic sustainability of their products and product systems.

The evaluation of eco-efficiency aims at optimizing the performance value of the product system on different levels, i.e., its raw materials, production, delivery, efficiency of use, or a mix of these. Value can be expressed in financial terms or in other forms, with one and the same result: doing more with less.

The steps of eco-efficiency evaluation of a product system include:

- The definition of the objective and the field of application of the assessment
- The environmental impact assessment
- The evaluation of the product system value
- The measurement of eco-efficiency
- The explanation of results (including the quality control of the evaluation)
- The reporting
- The critical review of the eco-efficiency estimation

Eco-efficiency can be considered realized by achieving the increase of the product or service value, the resource efficiency optimization, and the environmental impact reduction.

Eco-efficiency Measurement

The abovementioned definition by the WBCSD states that eco-efficiency is achievable if goods and services are produced at competitive prices meeting human urgencies and bringing quality of life by gradually decreasing the environmental impacts of products and resource exploitation during the whole life cycle management. Considering this definition, eco-efficiency accounting, aimed at the assessment phase, can be conducted through two main classes of measurement:

- Environmental productivity and its reciprocal, i.e., the environmental intensity of production
- The cost of environmental progress and its reciprocal, i.e., the environmental cost-effectiveness

Each of the indicators comprised in the two classes of measurement can be calculated for any unit conducting economic activities. This is possible because the latter always refer to cost and value, but also have a physical connotation, and thus unavoidably affect the environment (WBCSD 2000; Hupples and Ishikawa 2009).

The eco-efficiency indicators, mainly represented by ratios, can also be applied to a macro- or micro-level. The determination of the calculation methodology of eco-efficiency indicators at a micro-level can be conducted through the incremental eco-efficiency method, the win-win method, and the difference eco-efficiency method.

The first expresses the effects of the total value of a product system or alternatively its total connected environmental effects. The second method compares a historical reference situation, used as a benchmark, with new potential scenarios based on the use of innovations (Hupples and Ishikawa 2009). The third method, in line with the second, makes a comparison exclusively

Eco-efficiency,
Fig. 1 From eco-efficiency
 assessment to
 environmental policy.
 (Source: Personal
 elaboration)

between the two alternative innovations that potentially contribute mostly to the increase in eco-efficiency.

Since the ultimate goal of eco-efficiency assessment is to support the decision-making process toward optimality on a national/global scale (WBCSD 2000; Ruffing 2007; Huppel and Ishikawa 2009), scientific efforts are mainly addressed toward the improvement of macro-level measurements, which so far are less consistent and accurate (Ruffing 2007).

Policy Implications and Developments

Quantifying and evaluating eco-efficiency provides decision-makers with relevant information for drawing up policies addressed to sustainability, which, for example, consist in an expansion in environmental expenditure or a strengthening rule to avoid market failures. As shown in Fig. 1, assessing eco-efficiency through input- and output-oriented approaches support policymakers to evaluate if environmental policy should be addressed at minimizing input (natural resources savings) or maximizing output keeping constant input quantities (increased economic productivity) (Toma et al. 2016).

The policy strategies centered on the concept of eco-efficiency include Factor 4 and Factor 10 by WBCSD. Boulanger (2010) identified the key factors common to all eco-efficiency strategies, i.e., trust in technological innovation in terms of sustainability; companies as main drivers of transformation; trust in markets; and positive perception of growth.

The improvement of eco-efficiency, as a driving force for sustainability, has been questioned by Huesemann and Huesemann (2011). However, the new cradle-to-cradle and sustainable production and consumption approaches, assuming changes in lifestyles and production models, imply a key responsibility of companies as they consume and produce. The notion, the assessment, and the accounting of eco-efficiency can be useful tools for companies to achieve sustainable development, integrating two of its three axes, the economic and the environmental ones (Ehrenfeld 2005), making it easier to address social issues later (WBCSD 2000).

Summary

The term eco-efficiency originates from the fusion of two words, the noun “efficiency” and

the adjective “ecological,” coined in 1992 by the World Business Council for Sustainable Development. It refers to the managerial attitude that aims at decreasing ecological damage while increasing efficiency of the production processes; minimizing the use of energy, material, and water; recycling more by-products; and eliminating hazardous emissions or wastes. Quantifying and evaluating eco-efficiency provides decision-makers with relevant information for drawing up policies addressed at sustainable development, which, for example, consists in an expansion in environmental expenditure or a strengthening rule to avoid market failures. The notion, the assessment, and the accounting of eco-efficiency can be useful tools for companies to achieve sustainable development, integrating two of its three axes, the economic and the environmental ones, making it easier to address social issues later.

Definition

In general, the **Ecological Footprint (EF)** can be described as “a way to measure the impacts of

human activities on Earth.” (Mariam et al. 2019, p. 60), especially on biocapacity (Wackernagel and Beyers 2019). It is a measurement tool to determine human demand on – and supply of natural resources, usually expressed in equivalent global hectares. The calculation is applied to determine humanities natural requirements at the global, national, regional, organizational, or individual level. In particular, it calculates how much biologically productive land and water area is needed to produce the appropriate resources and absorb the waste generated by a human population (Wackernagel and Beyers 2016). The EF is currently the most appropriate measure to judge the scale of maximum sustainability within the planetary boundaries (Toderoui 2010) understandable without the requirement of in-depth specialist knowledge. It is thus accessible to a broad audience (Best et al. 2008). At the same time, it provides a clear basis and framework for political and economic decision-makers in order to better assess their actions and long-term responsibility towards nature. Since its implementation in 1997, it has been continuously developed and adapted to external conditions.

History

The Ecological Footprint approach dates back to the early 1990s, when Rees (1992) and Wackernagel (1994) criticized the prevailing, largely unquestioned, economic view of natural resource usage and pointed out the resulting irreversible overexploitation. Initially, examples largely focused on urban areas in which consumption and the resulting “import” of resources exceeded the actual production capacity of the largely sealed area. In subsequent years, Rees and Wackernagel (1996) developed the concept of the Ecological Footprint, an instrument whose application extends beyond the boundaries of urban areas and enables the measurement of the global extent of anthropogenic overuse of natural resources. In addition to this visualization, the instrument serves to answer questions about the limits and limitations of anthropogenic resource

consumption, the global allocation of natural resources and their global sustainable use (Wackernagel and Rees 1996).

The first systematic attempt to calculate the Ecological Footprint and the biocapacity of nations began in 1997. Building on this determination of global biodiversity assessments, the Global Footprint Network (GFN) was established in 2003 to provide well-founded arguments to push political decisions forward and to ensure that all people are able to live sufficiently within the earth’s available resources. In order to come closer to achieving these objectives, GFN cooperates with policy makers on global, national, and regional levels and provides an accounting framework that quantifies the annual supply and demand for key ecosystem services, the National Footprint Accounts (NFA) (Lin et al. 2018). NFA are based on UN data sources, which allow the resilient determination of the Ecological Footprint for over 200 nations and enables the calculation back until 1961. Nowadays, the calculations are updated annually and fed with the newest available data (Global Footprint Network 2020a, online; for more information, see “National Footprint and Biocapacity Accounts 2019 Public Data Package”).

Methodology

Conceptually, the Ecological Footprint is based on “area as currency” to ask the question “How much nature does everything cost?” (Wackernagel and Beyers 2019, p. 17). The approach is based on two main determinants: biocapacity and Ecological Footprint.

Biocapacity describes the sum of biologically productive land and sea area available on a local to a global level, which provide the ecosystem services that humanity consumes (Borucke et al. 2013). It consists of humanities ecological budget and nature’s regenerative capacity (Wackernagel and Beyers 2019).

Ecological Footprint is the sum of land and water areas that are needed to produce the anthropological needs and to absorb the waste generated (sink function). The biologically productive land

and water areas used for calculation are divided into the six following Footprints:

- Carbon: The carbon footprint refers to the amount of emissions released as a consequence of human activities (Tokuc 2015). It is closely linked to fossil fuel use and therefore global climate change. The CO₂ emissions are converted into biologically productive areas necessary for absorbing those (GFN 2020b).
- Cropland: Cropland is the most bioproductive of all the land-use types and consists of areas used to produce food and fiber for human consumption, feed for livestock, oil crops, and rubber (Econation 2020). Due to lack of globally consistent data sets, current cropland Footprint calculations do not yet take into account the extent to which farming techniques or unsustainable agricultural practices may cause long-term degradation of soil. The cropland Footprint includes crop products allocated to livestock and aquaculture feed mixes, and those used for fibers and materials.
- Fish: The fishing grounds footprint is calculated based on estimates of the maximum sustainable catch for a variety of fish species. These sustainable catch estimates are converted into an equivalent mass of primary production based on the various species' trophic levels. This estimate of maximum harvestable primary production is then divided among the continental shelf areas of the world. Fish caught and used in aquaculture feed mixes are also included (GFN 2020b).
- Forest product: Forest land provides for two services: the forest product footprint, which is calculated based on the amount of lumber, pulp, timber products, and fuel wood consumed by a country on a yearly basis. It also accommodates the carbon footprint, which represents the carbon dioxide emissions from burning fossil fuels. The carbon footprint also includes embodied carbon in imported goods. It is represented by the area necessary to sequester these carbon emissions. The carbon footprint component of the Ecological Footprint is calculated as the amount of forest land needed to absorb these carbon dioxide emissions. Currently, the carbon footprint is the largest portion of humanity's Footprint (GFN 2020b).
- Grazing: Grazing land is used to raise livestock for meat, dairy, hide, and woolen products. The grazing land footprint is calculated by comparing the amount of livestock feed available in a country with the amount of feed required for all livestock in that year, with the remainder of feed demand assumed to come from grazing land (GFN 2020b).
- Built-up land: The built-up land footprint is calculated based on the area of land covered by human infrastructure – transportation, housing, industrial structures, and reservoirs for hydropower. Built-up land may occupy what would previously have been cropland (GFN 2020b).
- Additionally, areas that cannot be used biologically (cultivated areas, but also deserts and high mountains) are treated as neutral (Global Footprint Network 2009, online).

In order to relate the two factors Ecological Footprint and biocapacity, a common unit of measurement is necessary. This was created by GFN (2009) in the form of the global hectare (gha). Globally, there are about 12.2 billion hectares of biologically productive area (Wackernagel and Beyers 2019).

The bioproductivity of natural spaces and areas is strongly dependent on various factors such as geographical location, soil composition, climate, and human activities of cultivation. The gha therefore indicates the worldwide average bioproductivity per corresponding area. Global hectare areas provide specific information that goes beyond the pure size and weight of water and land areas (Wackernagel and Beyers 2010). This information is standardized through the application of the following factors and thus makes it possible to present the results in a globally comparable unit of measurement.

- Yield factors (YF's) explain the different productivity of countries for certain types of land use.

- Equivalence factors (EQF) convert the areas of different land use types with their respective global average productivity into their corresponding areas with the global average bioproductivity across all land use types. The EQFs vary according to land use type and year (Borucke et al. 2013).

The presentation in global hectares allows the addition and comparability of the Ecological Footprint and biocapacity of a given area and land use type. Human needs can thus be applied both locally and globally and express in easily understandable indicators how much biologically productive land and water is needed to provide the necessary resources and absorb the human waste. Hence a country's Footprint is the sum of all the cropland, grazing land, forest land, and fishing grounds required to produce the necessary goods its inhabitants consume, to absorb emitted waste, the production of energy, and to provide space for their infrastructure (Wackernagel et al. 2002).

It is differentiated between countries that are ecological creditors and those that are ecological debtors. A country with a biocapacity that exceeds their EF of consumption is considered an Ecological Creditor, for example, French Guiana, Gabon, Congo, Central African Republic, Uruguay. A country with an EF of consumption that exceeds their biocapacity is considered an Ecological Debtor, for example, Singapore, Bermuda, Barbados, Israel, Saudi Arabia (GFN 2020c).

The NFA determined 12.2 billion hectares of biologically productive land and water on our planet in 2019. Divided by the world's population in that year results in 1.6 global hectares per person. This area also needs to accommodate the wild species that compete for the same biological material and spaces as humans. In industrialized countries, however, this value is clearly exceeded; in nonindustrialized countries, it is often undershot, but even in such countries, the gha required per person tends to increase in terms of usage and population growth (Kitzes et al. 2009).

Further sources of information: An individual calculation is possible under: <https://www.footprintcalculator.org/>

while an average consumption by country can be found under: <http://data.footprintnetwork.org>.

Global Footprint Network

Global Footprint Network is an international non-profit organization founded in 2003, which envisions a future where all can thrive within the means of our one planet by making ecological limits central to decision-making (Global Footprint Network 2020b, online).

National Footprint Accounts

National Footprint and Biocapacity Accounts (NFAs) provide the core data required for all Ecological Footprint analysis worldwide.

The Accounts measure the ecological resource use and resource capacity of nations over time. Based on approximately 15,000 data points per country per year, the Accounts calculate the Footprints of more than 200 countries, territories, and regions from 1961 to the present (GFN 2020a, online).

Earth Overshoot Day

Earth Overshoot Day is the day when humanity has exhausted nature's budget for the year. For the rest of the year, society operates in ecological overshoot by drawing down local resource stocks and accumulating carbon dioxide in the atmosphere. The first Earth Overshoot Day was December 19, 1987. In 2017, Earth Overshoot Day occurred on August 2 (Earth Overshoot Day 2020, online).

Limitations of GF

In a review of more than 150 original papers and 50 interviews with international EF stakeholders, Wiedemann and Barrett (2010) outlined a number of EF limitations that mainly still hold true today:

- Limited role in public policy
- Limited in scope
- Missing alignment with UN System of Environmental and Economic Accounting

However, since then, the tool described and the data generated by the calculation are widely recognized. In more than a dozen countries, including France, Germany, Japan, etc., the results are already being used as basis for political decisions. However, despite the broad acceptance, application and possibilities offered by the EF calculation, the methodological approach is subject to limitations.

As the most important limitation, the GFN (Ewing et al. 2008) itself mentions the non-consideration of the formation of carbon dioxide caused by the combustion of fossil fuels. For these emissions, the Ecological Footprint assumes an area consumption in the form of forest that would be necessary to biologically bind the CO₂ produced. In addition, other important greenhouse gases such as methane are not taken into account.

Critics also point out that biodiversity is equated with biocapacity. The conservation of biological diversity is therefore not taken into account and natural space is reduced to anthropogenic benefits. Water is also regarded as a biologically neutral “circulation quantity” that is neither consumed nor produced and is therefore not taken into account in the approach. However, both variables belong to the “planetary boundaries” that scientists regard as vital for survival and are therefore particularly worthy of protection (McManus and Haughton 2006). As a result, the condition and health of flora, fauna, and humans are subordinated to the production and service of nature.

A further point of criticism is the low level of consideration given to the use of nuclear energy and the associated environmental problems and risks. Due to the insufficient calculation of, for example, energy consumption, waste heat, risks of nuclear accidents, or the storage of nuclear waste, countries with a high proportion of nuclear power

have a lower Ecological Footprint than countries with a high proportion of renewable energies. Furthermore, the calculation is generally based on past burdens and does not make any predictions for the future. The immense effects of the reactor accident in Fukushima, Japan, show, however, that the consideration of risks is of great importance.

In addition, there are limitations regarding the inclusion of waste. These are divided into three categories (Borucke et al. 2013):

1. Biodegradable waste is considered “neutral” and is therefore not included in the calculation.
2. Landfillable “normal” waste, which should actually enter the land area necessary for long-term landfilling. At present, however, only anthropogenic CO₂ is included.
3. Materials that are not produced by biological processes or not absorbed by biological systems (in particular plastics, but also toxic and radioactive substances). They do not have a defined Ecological Footprint, other indicators are needed for such waste.

This means that ultimately no waste in the colloquial sense is covered by the Ecological Footprint. Recycling is not explicitly recorded as it “automatically” reduces the footprint.

Nonrenewable resources such as copper, tin, coal, and oil come from outside the biosphere and have no Ecological Footprint as defined by the methodology. The “secondary consumption” of production such as energy consumption and other material consumption can be taken into account. Fossil fuels are a special case of nonrenewable resources, as they are at least within the biological cycle, even if they come from another age. The area needed to biologically bind the released CO₂ is set for them. If one wanted to define an area that would be necessary to regenerate fossil fuels, one would come across footprints that would be many hundreds of times larger than those calculated today (Moffatt 2000).

Summary

One of the main challenges of today is undoubtedly to find a solution for the ever-increasing demand for nature and natural resources within the finite limits of planet earth and the dramatic effects human create. The ever-growing world population devours immense resources to meet basic needs alone. Added to this are the resource-intensive lifestyles of the western world and the emerging economic powers.

These circumstances increase the pressure on nature, whose life support systems are often already overloaded. To ensure long-term well-being and peaceful coexistence, it is essential to reduce the environmental impact of resource use and ensure the regeneration of natural cycles. However, there needs to be some form of measurement of earth boundaries.

The Ecological Footprint provides an approach to reflect the increasingly dramatic situation in which recent years of rapid growth and massive use of fossil fuels have led. It is a tool for expressing complex issues in a standardized and easily understandable form and for ensuring international comparability.

Yet, the limitations should not be neglected. Above all, the limited ability to include hazards and pollutants, the human health factor and the very strong economization of natural spaces and resources are consistently criticized. It is therefore important that those responsible take the criticism seriously and into account in further development. If this is achieved within a manageable timeframe, it is quite conceivable that the EF can serve as an important indicator for political and economic decisions and raise awareness of the urgency of action (Kitzes et al. 2009).

Introduction/Definition

Ecology is the scientific study of the interactions between living things and their environment's physicochemical components to comprehend the patterns these interactions cause in the geographic distribution and abundance of distinct animals (Schmitz 2013). Ernst Haeckel, a Darwin supporter, created the term “generelle morphology” in his book *Generelle Morphology*, published in 1866. According to Haeckel (1866), ecology is “the systematic study of organisms' relationships among themselves and their surrounding environment.” Abiotic and biotic ecosystem components and abiotic elements are all interconnected through nutrient cycles and energy fluxes (Tansley 1935). Ecosystem is the fundamental unit of ecology, consisting of autotrophic and heterotrophic components and abiotic influences (Odum and Barrett 1971). As a result, life processes in multi-species organism assemblages and their interactions with the abiotic environment impact ecosystem activity (Elmqvist et al. 2010).

Ecological processes enable the delivery of critical ecosystem services for human well-being (Costanza et al. 1997). Ecosystem services might be defined as people's ecological activities. In recent publications from the Intergovernmental Platform on Biodiversity and Ecosystem Services (IPBES), ecosystem services are described as nature's contributions to humankind (Díaz et al. 2018). This phrase incorporates positive and negative aspects of life that impact people's well-being. According to the Millennium Ecosystem Assessment, these positive contributions include providing, regulating, preserving, and cultural services (Leemans and De Groot 2003). It is critical to describe the analysis spatially and temporally when investigating ecological services. To govern the system to benefit both the environment and people, a plan that considers ecological conditions, service provision, and their consequences on people's lives must be developed (Alcamo et al. 2003).

Ecological Complexity and Organizational Levels

The environment's complexity might present itself in various ways (Loehle 2004). Ecosystems are well known in systems biology as complex adaptive systems (Hartvigsen et al. 1998). As a result, self-organizing systems grow under thermodynamic rules. Ecosystems will organize themselves such that energy degradation from incoming energy is hastened. They will change and adapt so that the ecosystem and its component systems have a better chance of survival (Schneider et al. 1994). Ecology studies organisms, populations, communities, ecosystems, landscapes, and the biosphere at many organizational levels, including the individual organism. Individuals and their interactions with their environment are organisms at the organismal level. Individuals of any species may be found in groups at the population level, valid for all species. A community, sometimes known as a “biotic community,” in an ecological setting comprises all the populations in a particular location (Odum and Barrett 1971). The interaction of live creature populations with nonliving environmental components as a system is referred to as the ecosystem level (Smith and Smith 2012). The word “landscape” refers to a collection of ecosystems that interact and are duplicated comparably over a vast region (Forman and Gordon 1986). In its ultimate form, the ecosphere is the world's most extensive and essentially autonomous biological system, including all of Earth's living species, which interacts with the physical environment to maintain a self-regulating and regulated pulsing state (Odum and Barrett 1971).

Ecosystem Ecology is the Study of Ecosystem Ecology

The two types of ecology are autecology (the study of individual organisms and populations) and synecology (ecology of the relationships among organisms and populations). Ecosystem

ecology is the approach used to execute synecology. The amount of energy or matter going through a system is considered the dimensional unit in the study of ecosystems (Jørgensen 2009). As a result, ecosystem ecology is concerned with the changes, movement, and accumulation of energy and matter in an ecosystem (Agren et al. 1998). The study of organisms' interactions with their environment is also included in ecosystem ecology (Chapin et al. 2011).

Over time, the phrase "ecosystem ecology" has grown and become more encompassing. The growing recognition of the interconnection of natural and social systems necessitates the use of holistic viewpoints (Raffaelli and Frid 2010). People's interactions with ecosystems are complicated by the importance of environmental consequences and services. Ecosystem ecology is the study of ideas derived from social-ecological stewardship that enables individuals to increase ecosystem resilience and human well-being due to social-ecological change (Chapin et al. 2011).

Ecosystem Services

According to MEA (2005), ecosystem services are the benefits that individuals get from ecosystems. They may also be defined as direct and indirect environmental benefits to human well-being (TEEB, 2010). This concept was motivated by the circumstances and means through which ecosystems and biodiversity aid human existence. These processes culminate in the creation of ecosystem goods (Daily 1997). As Costanza et al. (1997) defined, ecosystem goods and services are the benefits that individuals get from ecosystem functioning. According to more recent research, ecosystem services (together with other inputs) contribute ecosystem structure and function to human well-being (Burkhard et al. 2012a; Burkhard and Maes 2017). For ecosystems to provide benefits to humans, individuals (human capital), communities (social capital), and their built environment (built capital) must all be present. Therefore, ecosystem services may be regarded as a natural capital contribution to

human well-being that involves interaction with human, social, and constructed capital (Costanza et al. 2014). The Millennium Ecosystem Assessment (MEA, 2005) categorizes ecosystem services into four categories: provisioning services include food, raw materials, and energy (directly consumed by people). "Regulating services" are those that enable the regulation of other environmental media or processes. Cultural services are those that cater to people's cultural or spiritual needs. The term "supporting services" refers to ecosystem activities and processes that allow other services to operate (Lamarque et al. 2011). The Economics of Ecosystems and Biodiversity (TEEB) and the Common International Categorization of Environmental Services (CICES) are two different categorization systems that aim to better public knowledge of the ecosystem's benefits. Finally, the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES) approach proposes a core typology of values connected with nature and quality of life to guide policymakers in value assessment (IPBES 2017).

Approaches to Ecosystem Evaluation and Conservation

Ecosystem assessments are gaining popularity among scientists and policymakers (Maes et al. 2012). The Millennium Ecological Assessment (MEA) was the first global assessment to focus on the human impacts of environmental change. According to MEA results, 60% of the ecosystem services assessed have declined, creating problems to development, poverty reduction, and long-term environmental change adaptation measures (Haines-Young and Potschin 2010). In the face of global change, conservation efforts must strike a balance between the perspectives of socio-ecological systems and societal interests in ecosystem services, all while preserving ecosystem integrity and health (Ban et al. 2013; Palomo et al. 2014; Cumming et al. 2015). The ecosystem services approach (Cowling et al. 2008; Lopez-Hoffman et al. 2010) proposes conservation goals that include social, economic, and cultural

aspects of nature and intrinsic traits. The evolution of ecosystem-based management (EBM) is a method of considering the effects of management on multiple ecosystem services in an integrated systems approach. This example incorporates an ecosystem services approach into conservation and management while avoiding single-sector management, which has both socially and environmentally harmful “unintended consequences” (Christensen et al. 1996; National Research Council 1999; FAO 2003; Pikitch et al. 2004).

This EBM method provides managers with a framework for extending their perspectives and examining the numerous consequences of their decisions (Tallis and Polasky 2009). The economic value of ecosystem conservation is also essential for more effective biodiversity mainstreaming and a governance resource that can influence our individual and collective actions (CBD 2010). “Measuring” monetary values are necessary for better management decisions because they reveal ecological services’ socioeconomic relevance (Randall 1988; Daily et al. 2009). Spatial mapping of ecosystem services also helps accomplish various policy goals by allowing for the examination of trade-offs between service delivery at different levels (Troy and Wilson 2006; Naidoo et al. 2008; Vihervaara et al. 2010; Burkhard et al. 2012b). Quantitative geographic data may also be used to forecast net future gains or losses in ecosystem services and help build financial instruments for ecosystem investments (Maes et al. 2012). Since the European Commission’s professed goal for the Biodiversity Strategy to 2020 is to analyze ecosystems, there has been a growing need to evaluate and map ecosystem service supply and demand at all sizes, from transnational to small (Kasparinskis et al. 2018).

Summary

Comprehending ecosystems and their services are crucial for understanding nature’s ecological components and the connection of natural and social systems. Furthermore, including an ecosystem-based approach to conservation planning allows

for biodiversity protection while maintaining human well-being. This situation is a crucial step in the conservation process since it aids in the development of management plans and policy objectives. One method is to put a monetary value on ecological services.

Synonyms

Bioecology; Bionomics; Ecological system; Economy of nature; Environmental biology

Definition/Description

The term “ecology” (bioecology; bionomics; environmental biology; economy of nature) is derived from ancient Greek; oikos means “household, house, or place to live” (Smith and Pimm 2007) and logos “speech, word, reason” (Dictionary Merriam-Webster 2018). Ecology is focused on the distribution and abundance of organisms, the interactions among organisms and between organisms and their environment, and structure and function of ecosystems (Begon et al. 2006; Maastik et al. 2004; Schulze et al. 2005). Ecology includes subdisciplines such as autecology,

population ecology, chemical ecology, evolutionary ecology, physiological ecology, plant ecology, aquatic ecology, applied ecology, paleoecology, community ecology, ecosystem ecology, landscape ecology, and global ecology. It attempts to synthesize understanding from interactions between organisms (biotic components) and between organisms and their physical environments (abiotic components), and from the interplay between both of these (Biology dictionary 2016).

An ecosystem is a dynamic complex of organisms (plant, animal, and microorganism), their communities, and their physical environments (air, water, and mineral soil) interacting as a functional unit (Maastik et al. 2004). The biotic and abiotic components interact through nutrient cycles and energy flows (Begon et al. 2006). Ecosystems can be of any size but each ecosystem has a specific, limited space (Schulze et al. 2005). Some scientists view the entire planet as one ecosystem (Likens 1992; Hugget 2017). The ecosystem approach is fundamental to managing Earth’s resources because it addresses the interactions that link biotic systems, of which people are an integral part, with the abiotic systems on which they depend (Chapin et al. 2011).

Introduction

Ecology means different things to different people (Table 1). The general topics of ecology are, for example, the nature of ecosystems, energy flow in ecosystems, the biogeochemical cycles in ecosystems, the ecology of populations, the organization and dynamics of ecological communities, and ecology and man (Kormondy 1969).

With the exception of the last one, all other concepts are related straightly to the nature dimension. The last one is considered to represent either a social or a political dimension or a cultural or ideological dimension (Spooner 1984). According to Spooner, the nature dimension directs attention to the systemic relationships that compose natural reality. A meaning of a social or political dimension concerns on power. It depends on where the actor stands in relation to others in an ecosystemic whole.

Ecology and Ecosystem: Sustainability, Table 1 Topics, dimensions, and focuses of the term “ecology” (Kormondy 1969; Spooner 1984)

Topics (Kormondy 1969)	Dimensions (Spooner 1984)	Focus (Spooner 1984)
The nature of ecosystems	Nature	Systemic relationships
Energy flow in ecosystems	Nature	Systemic relationships
The biogeochemical cycles in ecosystems	Nature	Systemic relationships
Ecology of populations	Nature	Systemic relationships
The organization and dynamics of ecological communities	Nature	Systemic relationships
Ecology and man	A social or a political dimension; cultural or ideological dimension	Power; values

A cultural or ideological dimension again is based on values. While ecology has many meanings, its key is a synthetic perspective that combines ideas, concepts, and approaches.

Environmental problems such as global climate change, acid rain, the stratospheric ozone hole, tropical deforestation, toxic wastes, ocean dumping, and eutrophication are huge threats for ecosystems and also as a part of nature for human beings. An ecosystem is comprised of plants and animals, their physical environment, and interactions of these two parts (Fosberg 1963; Strahler and Strahler 1976; Tansley 1935). Aquatic and terrestrial ecosystems produce the resource base of people not only today but also in the future. People are fundamentally dependent on the ecosystem services produced by aquatic and terrestrial ecosystems. The ecosystem services include provisioning services such as food, water, timber, and fiber; regulating services that affect climate, floods, disease, wastes, and water quality; cultural services that provide recreational, aesthetic, and spiritual benefits; and supporting services such as soil formation, photosynthesis, and nutrient cycling (Millennium Ecosystem Assessment 2005). Thus the

need to understand the ecological linkages at the level of ecosystems is crucial also for management, and ecology is a very important science for enterprises and other work communities. Ecological production can produce new ecological innovations and enhance the competitiveness of enterprises and improve cost efficiency in the long term, being sustainable in both the short and long term in terms of social economy. Environmental concern and sustainable development is a key pillar of corporate social responsibility.

Key Issues

The term “ecology” (*Oekologie, Oecologie*) was introduced by Ernst Haeckel in 1866. His original definition of ecology focused mainly on animals (Likens 1992, p. 6):

By ecology we mean the body of knowledge concerning the economy of nature – the investigation of the total relations of the animal both to its inorganic and to its organic environment; including above all, its friendly and inimical relations with those animals and plants with which it comes directly or indirectly into contact.

However, rather than on organisms and species, Haeckel’s purpose was to focus attention on relationships, especially relationships with the environment (Spooner 1984).

Since 1866, a large variety of ecological specialities or subdivisions have been formed. For example, autecology deals with individual organisms or species; synecology is a branch of ecology that deals with the structure, development, and distribution of ecological communities (Dictionary Merriam-Webster 2018); physiological ecology studies the responses of single species to environmental factors; population ecology focuses on the abundance, distribution, and distributional factors of individual species; community ecology studies the number of species found at a given location and their interactions; and ecosystems ecology concerns the structure and function of organisms and their abiotic environment, and how the parts interact to generate the whole; evolutionary ecology operates at all levels (Hall and Weis 2012). In terms of human beings, human ecology entails the interaction

between human groups and their social and physical environments (Gazzola and Querci 2017). Landscape ecology in its part is a highly interdisciplinary science in systems ecology. It integrates biophysical and analytical approaches with humanistic and holistic perspectives across the natural sciences and social sciences. It is the science of studying and improving relationships between ecological processes in the environment and particular ecosystems (Sarkar 2005). In 2017, Hugget presented the term global ecology what means according him the science of the Earth ecosystem. Its object of study is the entirety of life (animals, plants, microbes) and life-support systems (air, water, and soil) on the Earth, variously referred to as the biosphere, the ecosphere, the global ecosystem, Gaia, and the Earth system.

In an attempt to bridge the spectrum of ecological approaches and to promote synthesis and integration, the scientific staff of the Institute of Ecosystem Studies (New York) has proposed a new overarching definition of ecology (Likens 1992, p. 8):

Ecology is the scientific study of the processes influencing the distribution and abundance of organisms, the interactions among organisms, and the interactions between organisms and the transformation and flux of energy and matter.

Thus, ecology stresses synthetic view of nature, not a fragmented one. The main goal of ecology is to promote a holistic understanding of the interaction among and between biotic and abiotic elements.

The term “ecosystem” has had quite a long history and at various times interest has been focused on different aspects of its meaning (Table 2). So, there are also several definitions of the term ecosystem.

Tansley (1935) stressed the interaction between its living and nonliving components when he introduced the term. According to him an ecosystem is comprised of the whole complex of plants and animals (biome) and their physical environment (habitat). He also stated that through interactions of these two parts the ecosystem is maintained in approximate equilibrium. Lindeman (1942, p. 400) in his part defined an ecosystem to be “composed of physical-chemical-

Ecology and Ecosystem: Sustainability, Table 2 Definitions of the term “ecosystem”

Definitions	Researches
An ecosystem is comprised of the whole complex of plants and animals (biome) and physical environment (habitat)	Tansley (1935)
An ecosystem is “composed of physical-chemical-biological processes, active within a space-time unit of any magnitude”	Lindeman (1942)
An ecosystem is a functioning, interacting system what is composed of one or more living organisms and their physical and biological environment	Fosberg (1963)
[An ecosystem] is “any unit that includes all of the organisms. . . in a given area interacting with the physical environment so that a flow of energy leads to clearly defined trophic structure, biotic diversity, and material cycles. . . within the system”	Odum (1971)
An ecosystem is a whole formed of nonliving and living parts interacting with each other. They also stated an ecosystem tends to achieve a balance of the various processes and activities within it	Strahler and Strahler (1976)
“The functional ecosystem is the conception where biota are explicitly linked to the abiotic world of their surroundings”	Allen and Hoekstra (1992)
Ecosystem is the complex of interconnected living organisms inhabiting particular area or unit of space, together with their environment and all their interrelationships and relationships with the environment	Ostroumov (2002)
An ecosystem is a dynamic complex of plant, animal, and microorganism communities, and their nonliving environment such as air, water, and mineral soil interacting as a functional unit	Maastik et al. (2004)
[In ecosystem] the living (biotic) and nonliving (abiotic) components interact through nutrient cycles and energy flows	Begon et al. (2006)
Global ecosystem is the ever-changing product of interacting biological, physical, and chemical processes. Life depends upon interaction between living and nonliving elements of the Earth	Hugget (2017)

biological processes, active within a space-time unit of any magnitude.” According to Fosberg (1963), an ecosystem is a functioning, interacting system what is composed of one or more living organisms and their physical and biological environment. Later on, Odum elaborated the term defining it by this way:

Any unit that includes all of the organisms (i.e. the “community”) in a given area interacting with the physical environment so that a flow of energy leads to clearly defined trophic structure, biotic diversity, and material cycles (i.e. exchange of materials between living and nonliving parts) within the system is an ecological system or ecosystem. (1971, p. 8)

Thus, Odum described explicitly the nature of interactions and the characteristics that contribute to and result from the interactions. He also clearly indicates that the ecosystem exists “in a given area” and is thus identifiable geographically. Later on, the view of Maastik et al. (2004) and Begon et al. (2006) supported Odum (1971) emphasizing interaction between the living (biotic) and nonliving (abiotic) components. Strahler and Strahler (1976) in their part defined the ecosystem as a whole formed of nonliving and living parts interacting with each other as Tansley (1935) also did. Strahlers also stated that an ecosystem tends to achieve a balance of the various processes and activities within it. So, ecosystems have inputs of matter and energy, used to build biological structure, to produce and to maintain necessary internal energy levels, but material and energy are also transmitted outside the ecosystem. Allen and Hoekstra (1992, p. 52) provided the alternate, concept-oriented definition:

The functional ecosystem is the conception where biota are explicitly linked to the abiotic world of their surroundings. Systems boundaries include the physical environment. Size is not the critical characteristic, rather the cycles and pathways of energy and matter in aggregate form the entire ecosystem.

Thus they defined a “functional ecosystem” to emphasize processes, matter cycling and energy flow, instead of structure. Within a landscape and structural features, they used the term “population-community” ecosystems.

In the 2000s, Ostroumov (2002) stressed space and time perspectives like Lindeman (1942):

Ecosystem is the complex of interconnected living organisms inhabiting particular area or unit of space, together with their environment and all their interrelationships and relationships with the environment. It is characterized by the description of populations (abundance) of individual species; interspecies relationships; activity of organisms; physical and chemical characteristics of environment; flows of matter, energy, and information; and description of changes of these parameters with time. (2002, p. 141)

In 2017, Hugget in his part presented the term global ecosystem. Global ecosystem is the ever-changing product of interacting biological, physical, and chemical processes. It was born and is transforming as a result of the activities of organisms. The actions of organisms are individual, but processes in the atmosphere, sediments, waters, and landscapes integrate the effects of their actions. Life depends upon its interacting with the nonliving world.

The ecosystem can be regarded as the fundamental ecological unit because a biotic community, including human beings, cannot be clearly differentiated from its abiotic environment (Figs. 1, 2, and 3). It provides a conceptual framework for the study of the interactions among individuals, populations, communities, and their abiotic environments, and for the study of the change in these relationships with space and time.

Ecological understanding is required to develop environmental policies and to manage resources for the benefit of human beings. The future of the world’s human societies still depends upon natural resources. In fact, water, croplands, forests, and grasslands underpin the world’s economy supplying raw materials for industry. Moreover, natural landscapes reduce erosion and filter pollutants from air and runoff water. They also reduce extremes of flooding and provide food and fiber. In addition, the ecosystem services support cognitive, cultural, and spiritual dimensions of human life. Although the world situation is partly better nowadays, for example, actions taken under the Montreal Protocol have led to decreases in the atmospheric abundance of controlled ozone-depleting substances and the start of the recovery of stratospheric ozone (WMO 2018), a renewed sense of individual responsibility is yet needed.

Ecology and Ecosystem: Sustainability,**Fig. 1** Forest. (Photo: E. Jeronen)

E

**Ecology and Ecosystem: Sustainability, Fig. 2** River. (Photo: E. Jeronen)

Such a sense of responsibility is vital for humans to manage, diminish, and attempt to prevent complex environmental problems.

The ecological responsibility of the commercial companies implies the integration of the environment protection requirements into the commercial activity (Mureşan et al. 2010). The goal of the ecological responsible action is “ecological sustainability” what refers to both environmental and social responsibility, ranging from issues of human rights to viability of local

communities and conservation of natural resources. The ways for achieving this goal may be a sense of personal ethical responsibility for restoring healthier communities and ecosystems; practices of renewal or involving minimal resources and waste in production and life activity; interconnectivity or acting with awareness of one’s relatedness to others in local, global, and biological webs and the impact of one’s actions on them; and promoting local well-being (Fenwick 2007).

Summary

Ecology (economy of nature) attempts to bridge the wide spectrum of ecological specialities or subdivisions by stressing synthetic view of nature. It integrates biophysical and analytical approaches with humanistic and holistic perspectives. Its goal is to synthesize understanding from interactions between biotic organisms, from interactions between organisms and their abiotic environments, and from the interplay between both of these.

Biotic and abiotic components and their interactions are properties of ecosystems. An ecosystem is regarded as the fundamental ecological unit which tends to achieve a balance of the physical-chemical-biological processes and activities within it with space and time. Understanding the ecological linkages at the level of ecosystems are crucial when developing environmental policies and to manage resources because human beings are fundamentally dependent on the ecosystem services produced by aquatic and terrestrial ecosystems. Enterprises and other work communities should utilize natural resources and raw materials in a sustainable manner,

thus reducing environmental pollution and climate change. Ecological sustainability concerns on issues of human rights to viability of local communities and conservation of natural resources. Ecological sustainability is not based only on corporations' ethical responsibility but also on individual ethical responsibility in everyday life.

Definition

The term economic sanctions refers to legally binding measures legislated by a governmental or administrative institution to reduce or to prevent commercial ties with a foreign official, entity, or country. Actors issuing sanctions include national governments, regional organizations such as the European Union, and international organizations such as the WTO and the United Nations Security Council, which has the right to impose coercive measures on UN member states for protecting and restoring international peace and stability. In difference to other means of

coercive diplomacy such as the cancellation of a sports event, economic sanctions unfold direct consequences for bilateral and international commercial ties including investment, trade, and access to credit for the sanctioned party creating legal obligations for domestic entities such as companies, banks, and even private persons. Economic sanctions tend to vary in scope and scale: Comprehensive measures target the counterparty's economy in its entirety, whereas smart or selective sanctions concentrate on specific entities for instance governmental organizations involved in human rights organizations or paramilitary groups.

Introduction

Economic sanctions are typically issued by governments or supranational organizations such as the European Union or the African Union in the form of a law or presidential decree and have the aim to reduce commercial ties with the targeted entity. On the contrary, the term boycott is more general. Although boycotts share the property of sanctions in the sense of measures to reduce or to stop commercial ties with a specific person, entity, or nation, the definition of boycott includes uncoordinated, informal, and spontaneous acts emerging from the population, driven by political groups within a country and directed against specific domestic or foreign actors. On the contrary, formal sanctions center exclusively on foreign actors outside of the immediate legislative reach of the sanctioning party including terrorist organizations, paramilitary units, or a foreign government officials. Comprehensive sanctions target the entire economy of the sanctioned country, whereas selective or smart sanctions target individuals or entities accused of violating norms of international law or human rights standards (van der Have 2020). The strictest form of comprehensive economic sanctions are embargoes leading to the complete prohibition of trade and investment, as it happened in case of UN Security Council Resolution 2397. Moreover, economic sanctions have manifold reasons and might originate in strategic considerations such as national interest

or issued as a reaction toward violations of human rights or international law (cf. Baldwin 2020). Due to its different focus, international sanctions need to be distinguished from extraterritorial legislation, which centers on general disclosures or certain compliance measures of companies to be taken in the event of human rights violations. In contrast to sanctions, normative implications deriving from extra-territorial legislation including the UK Modern Slavery and Human Trafficking Act or other legislation on supply chain with due diligence unfold no country-specific but rather general legal obligations to be realized by corporate actors (LeBaron and Rühmkorf 2019).

History of the Use of Economic Sanctions and Boycotts

Boycotts in general and economic sanctions in specific have accompanied human history arguably since the advent of statecraft. Early examples of the former include the boycott against the Hashemites (Brown 2004) or anti-Jewish boycotts in the nineteenth and twentieth centuries (e.g., Kreutzmüller 2015). More recently, boycotts or calls for boycotts have also been used or politically instrumentalized as a means to morally condemn the actions of specific companies or countries such as human rights violations. In 2019, boycotts hit Japanese companies, which did not apologize for war atrocities in Korea committed in the Second World War (Vekasi and Nam 2019). Likewise, human rights activists have been lobbying for boycotts in the cases of South Africa, Israel, Myanmar, and more recently China's Xinjiang province (cf. Kriebitz and Max 2020). Given a mixed record of historical experiences, some countries such as Germany and the United States have engaged in anti-boycott legislation to prevent discrimination and to coordinate foreign trade legislation. The US Anti-Boycott Act of 2018 for example prohibits "refusals or agreements to refuse to do business with or in a boycotted country," while anti-discrimination frameworks prevent boycotts on merchants or enterprises based on race, religion, and/or ethnicity.

The history of formal and legally formalized economic sanctions can be traced back to early writings on the role of sanctions as a "tool of statecraft" for enhancing national interest (Baldwin 2020; Blanchard and Ripsman 2008; Chan and Drury 2000). The acknowledgment of the economic factor in foreign affairs gave rise to coordinated sanctions appearing in the context of the Peloponnesian war (Brunt 1951) and later in the context of Napoleon's continental blockade. In the twentieth century, the U.S. economic sanctions have been formalized in the "Trading with the Enemy Act," which is still limiting trade to countries considered as adversaries. Likewise, the relevance of sanctions as tool of statecraft has been acknowledged in different versions of the National Security Strategy of the United States and other significant documents of key players in international affairs. More recently, the moral dimension of sanctions has become more pronounced, incorporated in the idea that sanctions are instruments to force leaders in authoritarian regimes to make concessions to human rights.

Current Use of Sanctions

In general, nation states are free to issue sanctions based on domestic and foreign policy considerations, what explains the wide use of sanctions in international politics. The decision with whom to trade, but also with whom not to trade is considered as domain and expression of national sovereignty. National sovereignty notwithstanding, UN member states are bound by some general principles in their conduct of trade relations. The Declaration on Principles of International Law concerning Friendly Relations and Co-operation among States and the Vienna Convention on the Law of Treaties set out that countries have to act in accordance with the *pacta sunt servanda* principle and need to stick to their agreements including trade agreements. This allows the sanctioned party to retaliate with counter-measures, when sanctions conflict with bilateral or international treaties. More recently, human rights and other elementary norms of international law (see

Belgium v Spain (Second Phase) ICJ Rep 1970 3 at paragraph 33) have emerged as an evolving part of the *ius cogens* of international law (see van der Have 2020). The elevated status of human rights as part of international law and the subsequent acknowledgement of obligations *erga omnes* in case of grave human rights violations have received support by the International Court of Justice in *The Gambia vs. Myanmar Case* (see Becker 2020). Consequently, many scholars of international law (Ainley 2008; Becker 2020) have argued that nation states have perhaps even a moral duty to engage in sanctions, when responding to gross human rights violations or other grave violations of international law. While the understanding of sanctions as means to deter human rights violations and aggression has received increased acceptance by scholarship, the conduct of sanctioning is less bound by specific constraints such as proportionality. This concerns limitations arising from domestic law as well. In the case of many nation states, the adoption, renewal, or lifting of sanctions rather belongs to the domain *reservé* of the nation state, where the executive branch has considerable room for interpretation (22 U.S. Code § 2798) (Drury 2000). In the case of the United States, the President has the power and right to impose economic sanctions, which has been exercised in the cases of the Russian Federation, the Islamic Republic of Iran, or other countries.

Apart from sanctions by individual nation states, the Security Council of the United Nations has a specific responsibility for global matters and a particular right to engage in sanctions. According to Article 41 of the UN Charter, the UN Security Council has a mandate by the international community to apply sanctions (Article 41) that must be complied with by all UN member states. In the past, the United Nations have typically addressed gross human rights violations or actions destabilizing international peace as it has happened in the case of Rhodesia, Rwanda, Iraq, and North Korea. This includes specifically the notion of crimes against humanity, including slavery, genocide or severe violations of *ius in bello* (see Sadat 2013). Sanctions on Rwanda have been imposed for ending the

genocide of the Tutsi, while coercive measures imposed on Iraq had the target of eliminating weapons of mass destruction and extended-range ballistic missiles. Likewise, sanctions imposed on North Korea for example have been driven by the nuclearization of the Korean peninsula and ballistic missile tests by the government of the Democratic Republic of Korea (e.g., United Nations Security Council Resolution 2371; United Nations Security Council Resolution 2375).

In addition to the United Nations, regional organizations such as the European Union or African Union have become increasingly active in issuing economic sanctions. Here, one can distinguish between in-group and out-group sanctions. In-group sanctions focus on the members of the organization violating standards defined by the organization including for instance rule of law standards, while out-group sanctions focus on entities outside of the organization. According to Article 7 of the Treaty on European Union, the EU can suspend rights of a member state violating the principles of the European Union enumerated in Article 2, pertaining to human rights, democracy, and minority rights. The suspension of specific rights might therefore result in economic consequences. In terms of sanctions targeting non-members, the European Union has defined the character of restrictive measures as a means “to bring about a change in policy or activity by the target country, part of the country, government, entities or individuals,” while the African Union refers primarily to “unconstitutional changes” (Constitutive Act of the African Union 2000, Article 4(p)). The EU Guidelines on Implementation and Evaluation of Restrictive Measures (Sanctions) in the Framework of the EU Common Foreign and Security Policy refer explicitly to freezing of funds and economic resources, restrictions on admission, arms embargoes, embargoes on equipment that might be used for internal repression, other export restrictions, import restrictions, and flight bans. Both the regional organizations base economic sanctions on a unanimous decision of the member states.

Critique on the Use of Economic Sanctions

Apart from the general legal debate on the permissibility of sanctions, scholars have discussed the moral and legal grounds for imposing sanctions. One can distinguish here between a more general debate on the purpose of sanctions, their effectiveness and norm collision with the rights of innocent bystanders and the critique on specific use cases of sanctions – for example, in the cases of Iraq, North Korea, or the Russian Federation.

Vague Purpose: Some scholars (van der Have 2020) comment on the use of sanctions based on the argument that the purpose of sanctions is often ill-defined and dominated by conflicting or blurring moral, political, and domestic considerations. Literature provides indeed different and partly conflicting interpretations concerning the aim behind sanctions. In *Economic Statecraft*, Baldwin (2020) has referred to the importance of economic sanctions as a means to realize the national interest of the respective state. From this perspective, one can derive that the purpose of economic sanctions is the realization of national interest by advancing geopolitical priorities such as containment of geopolitical adversaries. This understanding has been set forth in formal legislation and been incorporated in different national strategies (e.g., the US National Security Strategy of 2017). An alternative viewpoint derives the justification of economic sanctions from human rights obligations. Here, we encounter theories stressing the preventive character of coercive measures and theories stressing the punitive character (van der Have 2020). Emphasizing the preventive character implies that economic sanctions should have the purpose of forcing state or non-state actors to stop human rights violations. Thus, economic sanctions are perceived as a tool to enhance the costs of maintaining human rights violations such as forced labor. On the contrary, prioritizing the punitive understanding of coercive measures means that sanctions are understood as a means to punish perpetrators of human rights violations (Gordon 2011). The punitive character of sanctions connects to the debate on smart sanctions, which aim at holding individuals or groups

of individuals accountable for human rights violations, for example, by denying them entry to the country issuing sanctions or by freezing their bank accounts (compare: Global Magnitsky Act, Title XII, Subtitle F of P.L. 114–328; 22 U.S.C. §2656). Apart from the general critique on the purportedly ill-defined purpose of sanctions, some opponents of sanctions express the view that sanctions on the basis of human rights conflict with the general understanding of sovereignty. This is supported by adherents of cultural relativism, which argue that human rights do not represent a universally valid concept. Based on this, human rights-based sanctions are seen by some as a disguise for geopolitical ambitions and as a form of colonialism, as most sanctions have been issued by countries, which have been historically involved in colonialism (Wall 1998).

Efficacy: The debate on purpose connects to the debate on efficacy of sanctions, as it assumes a linkage between the real consequences of sanctions to the desired aims by the entity issuing sanctions. Scholars criticizing international sanctions argue here that sanctions often fail to realize their aims (Grauvogel and von Soest 2014; McMahon 2006; Peksen and Drury 2009), in terms of preventing international law violations such as stopping conflicts or preventing human rights violations. Some policymakers and organizations highlight the fact that international sanctions have an adverse effect on human rights and the resolution of international conflicts (Saunders 2014), as discussed in the contexts of international sanctions on Cuba and Iran (Hudson 2020; Office of the High Commissioner for Human Rights 2020). On the contrary, proponents of sanctions argue here that sanctions have been efficient and a driving force for ending gross human rights violations such as apartheid and refer not only to the economic but also to the psychological and social effect of sanctions, especially in the case of sanctions focusing on individuals (cf. Blanchard and Ripsman 2008; McMahon 2006).

Trade-offs: The debate on efficacy also entails further input for the debate on the potential trade-offs arising from the different consequences on sanctions. Although sanctions might realize their

goal, they might conflict with international norms as they generate negative consequences for different actors and third parties (Peksen 2016; van der Have 2020). One aspect which has been noted is the rule of law principle, which is at stake when sanctions are addressing individuals, which do not have the chance to defend themselves against the issuer of sanctions. Another aspect concerns the right of third parties. Some scholars have noted here that sanctions might create adverse impacts in terms of the right to development and medical aid. This has been discussed in particular in the cases of Iran and North Korea, where sanctions are attributed by some to have come along with a significant toll on civilians (Nebehay 2017).

Inconsistency: Another aspect of critique is that sanction regimes are regarded as arbitrary and inconsistent, implying that some countries accused of violating human rights or destabilizing international affairs are sanctioned while others are not. Research (e.g., Drury 2000) has demonstrated that “relations with the target country” and “domestic factors” play an important role in explaining sanctions. Further research has been added to these points and particularly with the aspect of the unanimous decision mechanism in regional organizations. Similar aspects are raised in the context of consumer boycotts (Vekasi and Nam 2019).

The critique on sanctions, which stems from fundamentally different ideological, historical or theoretical bases has led to a more detailed debate on sanctions. Consequently, contemporary sanction frameworks have rather addressed individuals than entire nation states following the 1990s, although comprehensive sanctions remain still common. However, smart sanctions themselves are subject to scrutiny and critique, as they involve elements of prejudice and as they might conflict with the right to a fair trial. For compensating for these limitations, scholars (Reinisch 2001) have called for a stronger integration of legal principles such as proportionality in the design and application of sanction frameworks or human rights accountability (Reinisch 2001), in order to create an alignment between desired aims, efficacy and the rights of other parties.

Summary

Economic sanctions are legal measures applied by nation states and international organizations with the aim to reduce or cease commercial ties with a foreign official, entity or country. Sanctions might be based on different considerations pertaining to national interest or moral objectives. Historically, sanctions of the United Nations have typically addressed gross human rights violations or actions destabilizing international peace. On the contrary, the motives behind sanctions by nation states are harder to identify.

The frequent use of international sanctions notwithstanding, scholars in international law are divided on the very purpose of sanctions. For some sanctions are punitive measures aiming to hold perpetrators of international law accountable, for others they depict instruments of political statecraft aiming at realizing concrete objectives such as human rights improvements or disarmament. Consequently, the use of coercive measures in general and sanctions in specific belongs to the more controversial areas in the discourse on the interplay between commercial exchange, sustainable development and human rights. As a result, this debate connects to more fundamental assumptions in international law on state sovereignty, moral universalism and proportionality.

Finally, the key challenge of the discourse on economic sanction is the integration of the different discourses on social development, human rights and international affairs, to help policy makers and international companies to navigate authoritarian regimes in acknowledging geopolitical realities and improving conditions for groups adversely affected by international sanction frameworks.

Economic growth and productive efficiency

Definition/Description

The definitions of economic sustainability are various depending on the approach and sustainability

label used. In the inside approach, economic sustainability is interpreted either from the perspectives of very weak or weak sustainability. The former stresses how organizations stay in business looking at the issues of corporate turnover and brand reputation and considering these to be at the heart of economic sustainability (Doane and MacGillivray 2001). The latter links the concept with productive efficiency and economic growth (Foladori 2005). Within a business context, this means using the assorted assets of the company efficiently to allow it to continue functioning profitably over time (BusinessDictionary 2018). Economic growth may take place at the expense of natural resources, ecosystem services, or welfare if the total capital stock is maintaining through time (Turner 1993).

In the outside approach, it is looking first at the economic impacts an organization has on society emphasizing thus strong sustainability position. Economic sustainability is understood as economic development without any loss of ecological or social sustainability. Economic capital cannot grow at the expense of natural or social capital. Economic sustainability means the allocation of resources over time (Markulev and Long 2013) and also intergenerational equity (Anand and Sen 2000). It emphasizes a production system which offers the highest level of well-being for current and future generations (Markulev and Long 2013) without compromising future needs (Basiago 1999). Economic sustainability, as one of the sustainability pillar (Elkington 1994), is necessary to maintain the natural, social, and human capital required for income and living standards.

Introduction

The concept “triple bottom line” was first articulated by Freer Spreckley in 1981 in his publication *Social Audit: A Management Tool for Co-operative Working*. In this work, he argued that enterprises should measure and report on financial performance, social wealth creation, and environmental responsibility. Later on, the phrase was articulated more fully by John Elkington in 1994 and 1997. For him,

sustainability is the balance between the three pillars: environmental, social, and economic (Elkington 1994, 1997, 1998). Goodland (1995) has identified the overlap and interaction among all these three sustainability pillars, particularly the strong linkage which is between “environmental sustainability” and “economic sustainability.” According to Klarin (2018), environmental sustainability focuses on maintaining the quality of the environment which is necessary for conducting the economic activities and quality of life of people. Social sustainability strives to ensure human rights and equality, preservation of cultural identity, and respect for cultural diversity, race, and religion. Economic sustainability in its part is necessary to maintain the natural, social, and human capital required for income and living standards (Klarin 2018).

According to Hediger (2000) natural capital is defined as the base of the natural resources in a specific geographic area. It consists of the capital of the ecosystem or environmental capital, which includes the stock of renewable resources (currently used and also unused in economic processes), partially cultivated and natural soil, as well as the environmental factors that are necessary for the functioning of ecosystems. It determines the overall quality of the environment in the area and stocks of nonrenewable resources (Hediger 2000). Social capital is about the value of social networks, bonding similar people and bridging between diverse people, with norms of reciprocity (Dekker and Uslander 2001; Uslander 2001). Social capital is defined by the OECD (2016) as “networks together with shared norms, values and understandings that facilitate co-operation within or among groups.” It includes also the economic resources garnered from human interactions (Investopedia 2018). Human capital refers to knowledge, experience, and skills of an employee (Ross 2015).

Key Issues

The notion of “economic sustainability” was originated by Hicks. Hicks (1946, p. 172) defined “income” as “a man’s income as the maximum

value which he can consume during a week, and still expect to be as well off at the end of the week as he was at the beginning.” Traditionally, economists assumed that the supply of natural resources was unlimited. They placed emphasis on the capacity of the market to allocate resources efficiently and believed that economic growth would bring the technological capacity to replenish natural resources destroyed in the production process. Nowadays it is known that natural resources are not endless enough.

There are two ways to approach economic sustainability. According to Doane and MacGillivray (2001), the first one starts with how organizations stay in business and approach the issue from the inside. The second one, taking the outside or stakeholder view, looks first at the economic impacts an organization has on society. This is coherent to the argumentation of researchers including both neoclassical and ecological economics. Based on these approaches, the definitions of the concept economic sustainability are various (Table 1).

The inside view stresses either very weak or weak sustainability position. From the perspective of very weak sustainability position, “...economic sustainability is the ability of an economy to support a defined level of economic production indefinitely” (Economic Sustainability 2018). With the words of Friedman (1970), “The business of business is business.” Nature has predominantly instrumental value (O’Riordan 1996), and the present generation have the right to use it (Davies 2013). It is also believed that economic growth is a valid measure of “progress” (Williams and Millington 2004). Consequently, development is based on unfettered free market (Davies 2013). Overall stock of capital assets remains stable over time, and complete substitution between human and natural capital is possible. There is a link between willingness to pay and sustainable development.

According to weak sustainability, economic sustainability is equated with productive efficiency and economic growth (Foladori 2005). It means (BusinessDictionary 2018):

Economic Sustainability, Table 1 Definitions of economic sustainability (cf. Doane and MacGillivray 2001)

Definitions	References
“... There is one and only one social responsibility of business – to use its resources and engage in activities designed to increase its profits so long as it stays within the rules of the game, which is to say, engages in open and free competition without deception or fraud”	Friedman (1970, p. 6)
“... Economic sustainability is the ability of an economy to support a defined level of economic production indefinitely”	Economic Sustainability (2018)
“Tomorrow’s Company uses its stated purpose and values, and its understanding of the importance of each relationship, to generate its own success model from which it can generate a meaningful framework of performance measurement”	RSA (1995, p. 1)
[Economic sustainability means] “the use of various strategies for employing existing resources optimally so that that a responsible and beneficial balance can be achieved over the longer term. Within a business context, economic sustainability involves using the assorted assets of the company efficiently to allow it to continue functioning profitability over time”	BusinessDictionary (2018)
Economic sustainability is one of the pillars of sustainability. It is necessary to maintain the natural, social, and human capital required for income and living standards	Elkington (1994)
[Economic sustainability means] that economic systems support sustainable social and environmental outcomes, where economics is the process through which humans create social and environmental outcomes	Zadek and Tuppen (2000)
“Economic sustainability [is] the process of allocating and protecting scarce resources while ensuring positive social and environmental outcomes”	Doane and MacGillivray (2001, p. 3.0.2)
“Economic sustainability refers to practices that support long-term economic growth without negatively impacting social, environmental, and cultural aspects of the community”	Economic Sustainability – Sustainability (2018)

The use of various strategies for employing existing resources optimally so that a responsible and beneficial balance can be achieved over the longer term. Within a business context, economic sustainability involves using the assorted assets of the company efficiently to allow it to continue functioning profitably over time.

Economic growth can take place also at the expense of other issues, such as natural resources, ecosystem services, or welfare if the total capital stock is maintained through time (Turner 1993). Weak sustainability is related to the precautionary principle or safe minimum standards. According to this principle, some natural capital is critical, that is, nonsubstitutable (Turner 1993). It limits set on natural capital usage and sees that economic sustainability requires the maintenance of natural capital, which is necessary in order to avoid economic degrowth (Bartelmus 2003). Thus, the economic capital produced by current generations must compensate the loss of natural capital for future generations by investment in renewable resource substitutes of equal value (Fiorino 2011; Gibbs et al. 1998). According to Hediger (2000), economic capital is defined as a generalization of the production capacity of certain economies; it is the potential for generation of income. It consists of produced capital, nonmaterial assets, and natural resources, which are harvested or developed for the use in the economic transformation process, and it also determines the macroeconomic performance (Hediger 2000).

Some researchers have expressed concern about economic action based on the ideas of very weak and weak sustainability. For example, Foladori (2005) wrote that if economic sustainability is understood in terms of efficiency or growth where only technical changes are considered, such a narrow view bears the risk that outcomes and policy recommendations lead to unsustainable lifestyle, production, and consumption patterns.

The outside or stakeholder view stresses sustainability in terms of nondecreasing natural capital representing thus “strong sustainability” position. According to Zadek and Tuppen (2000), economic sustainability means that

economic systems support sustainable social and environmental outcomes, where economics is the process through which humans create social and environmental outcomes. Also Doane and MacGillivray (2001) support this idea, and Van der Vorst et al. (1999) stress that economic sustainability requires environmental and social sustainability. The practical, scientifically valid, and ethical goal of business is to systematically and proactively maintain “the possibility that human and other life will flourish on the earth forever” (Ehrenfeld 2000, p. 36). The idea that sustainability is the equivalent of the ability of providing to the following generations the same level of non-renewable resources and/or quality of environment than enjoyed by the present generation is emphasized (Cabeza Gutés 1996).

Economic sustainability is thus understood to be economic development that cannot cause a loss of ecological or social sustainability. An increase in economic capital cannot be at the expense of a reduction in natural capital or social capital. Economic sustainability is interpreted as the allocation of resources over time (Markulev and Long 2013) and seen as a matter of intergenerational equity (Anand and Sen 2000). The concept implies a production system that offers the highest level of well-being for current and future generations (Markulev and Long 2013) and satisfies present consumption levels without compromising future needs (Basiago 1999). It means that the net effective capital stock (the contribution of knowledge and adjusts for depreciation) must grow at the rate of population growth (Markulev and Long 2013).

As it has been described above, there are various definitions and views about economic sustainability. Which of these ones should prevail is a question of values among individuals and societies, and full agreement has yet to be reached.

Chen et al. (2008) are worried about that many organizations focus their attention on economic sustainability alone when improving their profitability, competitiveness, and market share. They argue that this single-minded focus on economic sustainability can only lead to short-term success.

Gupta (2014) has stated that economic sustainability requires that the economy is growing in a sustainable way and that the benefits of economic growth are equally distributed over the long term. Economic sustainability is inextricably linked to both environmental and social sustainability. This is demonstrated by the limits to growth. Already in 1972, Meadows et al. posit that economies will not be sustainable if natural resources are used beyond the limits and if society continues to depend on phenomena that drove growth in the past. Human development is in relation to global carrying capacity, and when human development reaches the Earth's carrying capacity, exhausted natural resources cannot be changed either with natural or produced resources; in other words there is an absolute natural restraint of human development (Holden et al. 2014). Thus, organizations need to satisfy the sustainability of environmental, social, and economic capitals simultaneously in order to succeed in the long run (Dyllick and Hockerts 2002).

Summary

According to the term triple bottom line, sustainability depends on the balance between the three pillars: environmental, social, and economic. Environmental sustainability focuses on maintaining the quality of the environment, social sustainability strives, e.g., to ensure human rights and equality, and economic sustainability is important when maintaining the natural, social, and human capital required for income and living standards. Complete sustainable development is not easy to achieve, while a certain pillar of sustainable development becomes sustainable, others can become unsustainable, especially with regard to environmental sustainability, on which the overall capacity of development depends.

The definitions of economic sustainability are various depending on the approach and sustainability label used. In the inside approach, economic sustainability is interpreted either from the perspectives of very weak or weak

sustainability. From the perspective of very weak sustainability, "...economic sustainability is the ability of an economy to support a defined level of economic production indefinitely." The core idea is how organizations stay in business. Weak sustainability links economic sustainability with productive efficiency and economic growth. Thus economic sustainability means the use of various strategies for employing existing resources optimally so that that a responsible and beneficial balance can be achieved over the longer term. In the outside or stakeholder view, "strong sustainability" position is emphasized. According to it, economic sustainability means that economic systems support sustainable social and environmental outcomes, where economics is the process through which humans create social and environmental outcomes.

On the background of various definitions and views about economic sustainability are different values among individuals and societies. Full agreement has yet to be reached.

Synonyms

[Economic development](#); [Economic growth](#); [Economic sustainability](#); [SDGs](#); [Sustainability](#)

Definition

There is no consensus and institutional aspects on the definition, in general, economic sustainability indicates to implications or policies that support long-term stability in economic growth without negatively effecting social, environmental, economic, and institutional aspects. Well-known definition for the concept of economic sustainability

is provided by Solow (1974, 1991). According to him, economic sustainability refers distributional equity of capital for well-being to satisfy ourselves and future generations (Solow, 1974, 1991). Solow emphasizes that economic sustainability is a kind of moral obligation not only for future generations but also for those whose living standards are relatively low. In his famous paper “Sustainability: An economist’s perspective” (Solow, 1991), he emphasizes that:

... Sustainability as a moral obligation is a general obligation not a specific one. It is not an obligation to pre-serve this or preserve that. It is an obligation, if you want to make sense out of it, to preserve the capacity to be well of, to be as well off as we . . .

On the other hand, Milton Friedman as a founder of monetarist economic thought defines sustainability as “the business of the business is business” (Doane & Macgillivray, 2001).

Solow’s view can be explained as to save today’s economic opportunities (capital stock) to intergenerational well-being equity or for the future. So, it is not necessarily to increase capital stock. (Anand & Sen, 2000). Similar definition is proposed by Repetto (1985): The term economic sustainability is based on the living standards which suggest that because of resource scarcity, the economic system should be managed to maintain the resources for future generations that will be able to live in more equal living standards. Thus, for long-term economic sustainability both resilience and efficiency generally mean greater economies of scale are necessary (Goerner et al., 2009).

Introduction

The term sustainability became a widely used concept after the declaration of Brundtland Commission Report titled “Our Common Future” by WCED (, 1987) which defined it as “development that meets the needs of the present without compromising the ability of future generations to meet their own need.” (Anand & Sen, 2000).

Moreover, there are four pillars of sustainability: environmental, social, human, and economic.

Economic sustainability has four dimensions: economic, social, environmental, and institutional. Each of the dimensions is complex and interrelated. Thus, the term sustainability indicates to maintain the ability, capacity, and survival of each subtitle or dimension of sustainability (Spangenberg, 2005). So the main goal of the economic sustainability is to develop long-run sustainable values for all these dimensions. In more detail, environmental sustainability indicates physical environmental and natural resources and any implications to return to natural resources (natural capital) including recycling, renewable energy, drinking water, soil, fisheries, forests, sanitation (also known as ecological footprint), etc. Most of the debate on economic sustainability is based on environmental issues. Second, institutional sustainability refers to the implications or policies of particular institution regarding any institutional context of a particular institution including organizational structure, facilities, functions, etc. Third, social sustainability refers any policies or implications to improve or maintain social and human well-being supporting the ability of future generations (Spangenberg, 2005). If the forecasting about economic sustainability is reliable, economy is able to achieve long-run sustainability with all dimensions at micro and macro level (Doane & Macgillivray, 2001). So the main goal of economic sustainability is to maintain all the available resources in the long run.

The United Nations (UN) Sustainable Development Goals (SDGs) are a crucial tool toward economic sustainability. The seventeen development goals under the SDGs declared to reduce economic imbalances. In this context, these goals focus on the priorities which reduce inefficiency, effectiveness, uncertainty, and risk to maintain the resources in the long run. According to the SDGs, the priorities are reducing income inequality, poverty, unemployment, and wasting scarce resources by considering environmental elements (Niekerk, 2020).

Theoretical Debate

From Adam Smith, interest in economic sustainability is not the new debate in science economics. The main question of science economics is mainly about how we allocate scarce resource or how to achieve optimal or efficiency level of using these resources for human well-being. In the light of this framework, Classical economic thought assumed that supply and demand equation gives this balance (Doane & Macgillivray, 2001).

As of today, sustainable growth rate implicitly refers to the economic sustainability by economists as well as policy makers. In the economic theory, sustainability is mainly discussed as a part of economic development. Under this framework, much of the economic debate refers that the criteria of economic sustainability are based on innovativeness, and competitiveness (Rennings, 2000). On the other hand, the traditional criteria components of aggregate demand such as consumption and investment play a minor role in current literature (Spangenberg, 2005).

The below figure explains the economic sustainability interlinkages. According to the figure, economic sustainability analysis is set of the institutions of society as a source of social capital, the population as a source of human capital and the environment as a natural capital. Thus, the capital is the main determinant of economic sustainability and economic sustainability interrelated with social, environmental, and institutional sustainability (Spangenberg, 2005). In more detail, environmental sustainability refers any applications to sustain natural resources such as renewable energy or sustainability in human capital refers any applications to adequate education system. Additionally, institutional dimension indicates the reliability of legal and administrative framework (Fig. 1).

Summary

Economic sustainability refers applications and policies which support long-run economic growth

Economic Sustainability and Development, Fig. 1 The economic sustainability interlinkages. (Source: Spangenberg, 2005)

and development without negatively impacting the scarce resources. On the other hand, economic sustainability implicitly refers that sustainable steady GDP growth rate is around 2%. In the macroeconomic debate, the main criteria for economic sustainability are based on the “balance” like international trade balance, stability in overall price level, more equal income distribution, and sustainable debt levels. Thus, sustainable development and steady growth rate are usually implicitly assumed to be part of the concept of economic sustainability.

Description

An abbreviated form of ecological sustainability is eco-sustainability. It refers to ecological contributions to sustainable development made highly efficient and effective. The term “efficient” refers to the use of as few natural resources as possible in any activity, and “effective” means using the right resources or conserving them to encourage more sustainable behavior. Innovation may refer to each phase, input, process, and output. Innovation also relates to the degree and extent of a novel product, service, procedure, or process that is unknown to the organizational form ranging from a single business organization to the whole industry. Innovation should create some type of value (typically financial) and build competitiveness. Eco-sustainability innovations result in the more efficient distribution of natural resources or their complete conservation within a social activity or business operation. Solar technologies, information technology, water-filtering systems, recycling initiatives, and other technologies leading to lower amounts of natural resources consumed or their complete replacement are all examples of eco-sustainability innovations. In short, eco-

sustainability innovations capture any sustainable positive environmental effect irrespective of its origin, size, and form. So, it relates to both technological and nontechnological innovations.

The second portion of the definition covers the field of performance measurement. In general, performance measurement is a set of methods for assessing qualitative and quantitative aspects of present business activities or end products, and their environmental effects. It is a complete measurement of any form of output/outcome, which generates reliable data on the effectiveness and efficiency of business activities. In traditional business management, performance measurement is typically a component of the company's control and analysis process to guarantee that the organization achieves its maximum financial gain. In distinction, sustainability management has to do with evaluating the company's success from a balanced economic, environmental, and social perspective. The meaning of performance is incorporated into the idea of environmental sustainability. The specific way with which a business uses natural resources determines whether it follows the sustainability principle. This notion defines whether something contributes to sustainable development or not.

The Importance of Sustainable Performance

Different stakeholders are constantly searching for innovative ways to reconcile the goals of economic growth, social justice, and environmental protection. Due to the negative impact that humans have on the environment, a transition is required to a zero or positive impact on the environment. Over the previous two decades, the environmental factors have undergone a dramatic and dynamic transition in reach, scope, depth, and orientation, so the term "sustainability" has gained widespread usage in everyday speech. Environmental issues used to be seen as a constraint to business growth; now they are seen as one of the core drivers of economic development

(especially from the EU perspective). In every society, humans face a broad range of challenges that used to be constraints, such as environmental protection, hunger, poverty, uneven resource distribution, biodiversity, gender equality, equal opportunity, and renewable energy, among many more. These sustainability challenges have formed a common framework and need for rethinking our civilization in future. Sustainability has become a common term in business, politics, technology, and culture because of the range of societal and environmental issues addressed by the sustainability platform. This broad framework encourages diverse types of sustainability innovation, performance, and measurement.

There is no doubt that innovations in technology and its applications have aided the progress of humanity, but it also must be acknowledged that civilization came to the point where it has to examine carefully if some sorts of technology are harmful to the Planet. As Watts (1999) points out, if technology only relies on linear thinking, it will harm the environment. However, modern technologies enable the necessary changes by providing new holistic solutions.

Eco-sustainability innovation is a dynamic concept that is not only important for our present convenience and for making our lives easier but also necessary for our long-term survival. Its role in society has only increased and gained in importance as anthropogenic causes of environmental degradation have increased (Azevedo, Brandenburg, Carvalho, & Cruz-Machado, 2014). Natural, "green," or ecological components are the source and real provider of any form of value generated or introduced in modern society. Human insights and emotions need resources from nature (plants, vegetables, fruits, for food). Extraction of natural resources is an inherent part of every creature's everyday existence. The issue is how to make the most of this extraction long term. The closer people get to nature, the more they are conscious of the natural constraints of their consumption. They understand that if they consume all the accessible food, wood, or water for 1 year, they will not be able to do so again in

subsequent years and beyond. The use of natural resources becomes more complex and apparent as production methods are improved. Technology and its advancements play an important role in organized manufacturing. Because they increase resource extraction efficiency, innovations are always useful.

Defining eco-innovation is not an easy task. As Colombo, Pansera, and Owen (2019) concluded, this is not a stable, monolithic concept but interpreted flexibly and subject to multiple, often contested, framings, and definitions. Fussler and James (1996) define eco-innovation as “the process of developing new products, processes or services which provide customer and business value but significantly decrease environmental impact.” Andersen (2002) defines environmental innovations as “innovations which are able to attract green rents on the market.” Driessen and Hillebrand (2002) state that green innovation “does not have to be developed with the goal of reducing the environmental burden,” but it “does, however, yield significant environmental benefits.” According to Kemp and Pearson (2007), eco-innovation is “the production, assimilation or exploitation of a product, production process, service or management or business method that is novel to the organization (developing or adopting it) and which results, throughout its life cycle, in a reduction of environmental risk, pollution and other negative impacts of resources use (including energy use) compared to relevant alternatives”. OECD (2008) defined eco-innovation as “the creation of new, or significantly improved, products (goods and services), processes, marketing methods, organizational structures, and institutional arrangements which, with or without intent, lead to environmental improvements compared to relevant alternatives.” Oltra and Saint Jean (2009) follow OECD’s, and Kemp and Pearson’s, definition and define environmental innovation as “innovations that consist of new or modified processes, practices, systems and products which benefit the environment and so contribute to environmental sustainability.” Arundel and Kemp (2009) partly adopt OECD’s definition and emphasize that eco-innovations “can be

motivated by economic or environmental considerations.” Andresen (2010) concludes that “eco-innovation concept unifies environmental and economic goals in emphasizing green competitiveness as a core driver for environmental improvement; in relation to policy, it seeks to forward greater synergy between environmental and innovation policy.” These examples illustrate the wide variety of notations, and the terms eco-innovation, environmental innovation, and green innovation are used interchangeably, and the perception of the related field has broadened from a focus on “greened” products or processes to the coherence of environmental aspects of physical items, virtual structures, and organizational procedures (Azevedo et al., 2014).

As Heidenreich, Spieth, and Petschnig (2017) stated, although the benefits of eco-friendly innovations for reducing emissions from industry and transportation are well known, companies sometimes invest heavily in such innovations while few customers are willing to adopt them (e.g., alternative fuel vehicles). The goal is to figure out whether something is sustainable and, if so, how to measure its contribution. Straková (2015) notes that the way a modern company handles (and dedicates to) its financial performance is almost identical to the way it handles its sustainability performance.

Innovations and Eco-sustainability Performance Measurement

At the corporate level, environmental sustainability must be assessed as accurately as possible and, if possible, quantified in monetary terms. The following are examples of quantifiable environmental effects: cubic meters of water or wood used, kWh of electrical energy consumed, kg or ton of paper or plastics utilized, and metric tons of greenhouse gases emitted.

There is a dispute over whether a firm should create such a large amount of value per environmental effect or if the impact decreases in order to be eliminated (as the value rises). It became an issue of maximizing production and minimizing

natural resources. Only drastic ecologically aware innovations may enable long-term changes in the ratio of generated value to ecological effect. It is important to note that Colombo et al. (2019) came to conclusion that “in the EU programmes has mostly become constructed around the notion of eco-efficiency” completely ignoring its complex and dialectic nature. In that sense, the most suitable approach is that of Figge and Hahn (2004), who address this issue with two variables: eco-efficiency and eco-effectiveness. Figge and Hahn addressed the issue of maximization or minimization by understanding eco-efficiency as a ratio of value created per environmental impact added (2004: 175). In short, they sought to maximize or minimize the process.

Callens and Tyteca (1999) added the notion of efficiency to their basic principles, which emphasized a metric of sustainability performance that reflected how much environmental resources were compared to the company’s economic activities. The study of Figge and Hahn demonstrated the significance of innovation in promoting sustainability, while their research resulted in a unique sustainability indicator called Sustainable Value Added (SVA). SVA is the amount of value added by companies that use natural resources more efficiently than other companies in the benchmark, allowing them to create more SVA. This affected sustainability assessment research, which had previously focused on businesses that invented ways to be more efficient than their competition in utilizing or conserving natural resources. The measurement of sustainability performance is always linked to innovations in the field of ecology or the environment protection, i.e., the so-called “green innovations.” Green innovations that make a sustainable contribution are distinguished in numerous new economic terms and business platforms such as eco-preneurs (Pastakia, 1998), eco-management (Vibert, 2004), eco-product, or/and eco-innovations. According to Birchall, Chanaron, Tovstiga, and Hillenbrand (2011), there is a measurement crisis of innovation performance as there are so many different models and instruments attempting to capture too many things,

some of which are not even important. It is important to add that some of these innovations cannot be quantified. In addition to that, we should not forget the main reason for measurement is to raise efficiency and effectiveness of decision-making process.

Green innovations also require organizational renewal to enable companies in translating sustainability goals into business strategies and operations (Taneja, Pryor, Gibson, & Toombs, 2012). Eco-innovation is the only effective way for companies to take serious steps to reduce their negative impact on the environment. Eco-innovation is made up of two elements: eco-product innovation and eco-process innovation (Sezen & Cankaya, 2013). Innovation as a product or a process for company growth is unquestionable; the question then becomes what sort of innovation is appropriate to help businesses achieve corporate sustainability objectives. According to García-Granero, Piedra-Muñoz, and Galdeano-Gómez (2018), the top 30 company performance indicators cited by academics are divided into four distinctive categories: product, process, organizational, and marketing. According to a meta-analysis conducted by Kuo and Smith (2018), propelling eco-innovation via R&D is the ideal approach for businesses when contributing to sustainability. This, in turn, demonstrates that no other initiative, not even the development of new technologies and materials, processes, and their continual transformation, can make a significantly greater impact.

According to Roscoe, Cousins, and Lamming (2016), the sustainability component of any innovation is provided by supply networks in their three-stage typology for eco-innovation growth. In this situation, the firm benefits from developing strong relationships with important suppliers because their R&D spills over to the company throughout the new product development process. In this scenario, small suppliers may provide innovative solutions. By this example, developing connections with tiny vendors might lead to significant ecological progress. A clear and measurable aim must first be decided to measure anything. There are several goals connected with

various sustainability concerns when it comes to long-term viability. A specific list of critical sustainability indicators or variables must be established for each firm when measuring environmental sustainability. These indicators must reflect the main aspects of the company's sustainability in relation to its core activities. For example, the following quantities can all be determined in a manufacturing firm: water consumed, electricity consumed, paper consumed, and plastics consumed, and related to that: recycled water, electricity from renewable resources, recycled paper, and recycled plastics.

For each energy variable, the proportion of fossil or renewable energy may be determined. This way, there are already eight variables that can be measured before and after the introduction of innovations that are expected to lead to positive eco-sustainability outcomes. The change in these variables' values is equivalent to the new value generated by the innovative technology in a sustainable manner (Fig. 1). The term "eco-sustainable" is then used to describe innovation.

The environmental impact of each innovation is determined by a variety of combinations. The sustainability dimensions for a specific invention vary materials, design, energy, user experience, maintenance, health, lifetime, and recycling period. The findings of Carrillo-Hermosilla, Del

Río, and Könnölä's (2010) study suggests that the capacity of eco-innovations to create new business possibilities and encourage sustainable societal change is dependent on the integration of sustainability dimensions into the innovation process.

One thing is certain: A wide range of models for assessing performance results from the diversity of solutions in environmental sustainability. An innovation, for example, might only refer to the ecological optimization of water usage in a production cycle. Water consumed, the water discharged, water reused or recycled, and water price/cost are some examples of performance indicators. In complex business processes, the evaluation of eco-sustainability innovations becomes more difficult. As a result, different measurement initiatives, such as the Global Reporting Initiative, have taken the lead in addressing this issue by attempting to establish a wide range of universal sustainability performance metrics across various industries and procedures. Sustainability management and performance management are two distinct but related concepts. The integration of financial and nonfinancial measures creates the incentive for organizations to focus on the holistic approach that considers all pertinent organizational variables, such as quality, customer experience, market access, supply chain operation

	Resource consumption				
Innovation effect	Electric energy (kWh)	Used water in cubic meters (m ³)	Paper (m ³)	Plastics (m ³)	Units of production
<i>Before</i>	1.200	50	1,2	3,5	170
<i>After</i>	970	35	0,9	2,9	230
	Sustainability ratios= Resource/unit of production				
<i>Before</i>	7,059	0,294	0,007	0,021	
<i>After</i>	4,217	0,152	0,004	0,012	
Difference between <i>Before</i> and <i>After</i> Sustainability ratios represents the area of sustainable performance caused by eco-innovations					

Eco-sustainability Innovations Performance Measurement, Fig. 1 The sustainability performance caused by eco-innovations

efficiency (such as product innovation), and business competitiveness, among others. García-Quevedo, Kesidou, and Martínez-Ros (2020) confirm the significance of nontechnical types of eco-innovation, such as environmental management systems (EMS), noting the cross-sectoral implementation of ISO 14001 in relation to energy consumption and pollution intensity as an example.

Based on all these characteristics of sustainability, it can be concluded that the measurement of sustainability performance can be represented as a creative grid of sustainability elements specific to each company or organization (Fig. 2).

The multidimensional approach outlined above is critical to understanding how innovative, long-term success is achieved through multidimensional connections. Every study and meta-analysis of business ecology innovations addresses and validates the multidimensional perspective described above (Karakaya, Hidalgo, & Nuur, 2014). There is a basic principle, and that is to evaluate if consumer-friendly eco-sustainability solutions are effective mechanisms for mitigating the harmful effects of business on the environment. This can only be

achieved by considering specific characteristics of every company, such as its organizational structure, culture, processes, environmental impact, employee characteristics, market share and focus, specific product development aspects, types of stakeholders, etc. Each company creates its own performance grid when it comes to eco-sustainability innovations.

Other Business Issues on Eco-sustainability Innovations Performance Measurement

Although many firms have a clear mission, they do not always apply it in their everyday operations. This can involve developing environmentally friendly products and services that address the needs of customers rather than only meeting demand to generate value. Not only business innovations should improve the value of the company in financial terms, but also this must be done at all levels and contents of the value creation process. This places ecological operational performance on a higher level in sustainability management. The eco-efficient content of a firm must

Eco-sustainability Innovations Performance Measurement, Fig. 2 Eco-sustainability Innovations Performance Measurement Grid

capture both financial, environmental, and social aspects of sustainable value. Using different metrics, such as the Innovation Patent Index (IPI), companies can assess innovation and innovation performance (Ponta, Puliga, & Manzini, 2021). The IPI is used to evaluate different aspects of corporate innovation and its application. A high IPI indicates that a firm's innovation may result in higher eco-sustainability performance within a short time abroad in different industries at the international level.

Another consequence is the use of green manufacturing/production. Even environmentally friendly companies employ ecologically beneficial technology to boost production efficiency. It is also worth noting that environmental sustainability is a continuing process that always results in an increase in organizational or business efficiency. The continuity of the environmentally sustainable innovation process is driven by the demand for high-quality products that have little or no environmental impact. Green production is always intended to reduce negative environmental effects, as it is in its nature. Green advances may help restore damaged natural resources for some types of manufacturing. The greatest illustration of this is a technology that captures carbon dioxide in a manufacturing process and converts it back into oxygen or the production of useful liquids like ethanol, or nanomaterials that can be utilized in the circular economy.

Summary

This entry presents the definitional context and sustainability relevance of innovations that improve environmental performance. There is general belief among various stakeholders that the introduction of greener technologies and more efficient and effective environmental management could help reduce the costs of environmental protection and contribute to economic prosperity. The principle of sustainable development requires eco-sustainability performance in

all processes and organizational forms. Eco-innovations improve sustainable performance in terms of efficiency and effectiveness, which can be measured using adaptable eco-indicators for individual industries. Eco-innovations should be evaluated as any technological or process improvement that ensures a more sustainable impact. Measuring the performance of environmental sustainability is a significant challenge for CSR. To measure the performance of eco-sustainable innovations, a variety of CSR indicators need to be defined for a given company or organization. Performance measurement in this sense is conducted as a set of indicators that are considered in managing the implementation and outcomes of environmentally sustainable innovations. Performance measurement of eco-sustainable innovations is primarily a combination of their technological impacts, social aspects, qualitative elements, and eco-efficiency quantification. The business outcomes of eco-innovations within industries can only be evaluated using a multidimensional sustainable performance framework, which is presented in this entry.

Description

Education for sustainable development (EfSD, ESD; hereinafter ESD) is based on two concepts: education and ► [sustainable development](#). The term education means “systematic schooling and training for work.” It is based on the Latin word “educare” (“bring up, rear, educate”). In a narrow sense, education refers to the process of passing on the knowledge and skills to be learned from one generation to the next. In the broadest sense, it refers to any act or experience that affects an individual’s mind, character, or physical ability (Jeronen 2012). According to Brundtland, sustainable development is a process

of change that improves the livelihoods of present and future generations without compromising the Earth's carrying capacity (WCED 1987). It is considered to have three dimensions: an ecological or an environmental dimension, a social and an economic one (Fien et al. 2009).

ESD is holistic and transformational, lifelong learning process which aims to enhance the cognitive, social, emotional, and behavioral dimensions of learning (UNESCO 2017b). It has been part of the sustainable development debate and decision-making process since 2009 (UN 2009). It is seen as an innovative concept that gives new meaning to the teaching and learning of sustainable development. It has contributed to the debate both on the learning objectives, content, and pedagogies needed for the transition to ► [sustainability](#) including future education; peace education; citizenship education; gender equality and respect for human rights; health education; education for the protection and management of natural resources; and education for sustainable consumption (Wals and Kieft 2010, p. 7). ESD seeks to balance human and economic well-being while taking into account cultural traditions and the sustainable use of the earth's natural resources. Key issues affecting ESD include, for example, globalization, the rise of the information and knowledge society, the utilization of diversity, and the need for the inclusion of marginalized groups and perspectives. ESD's practical perspective offers a holistic opportunity to teach and study issues and phenomena not only in formal education but also in non-formal education (Barth and Michelsen 2013).

The Beginning and Development of the Global Action Program

The Tbilisi Conference (1977) had a decisive impact on our understanding of the importance of environmental education (EE) from school education to lifelong learning. The aim of EE was to increase environmental awareness, develop skills to acquire and use information, develop environmental attitudes, and enable participation (Michelsen and Wells 2017). Since the

Tbilisi Declaration (1977), students' awareness of environmental problems and related practical skills have been developed through EE (Table 1) (UNESCO and UNEP 1977).

In 1987, Brundtland's report, "Our Common Future," set out a "global agenda for change" that included ideas for justice within and between generations; long-term goals for sustainable development, cooperation, and new forms of management (WCED 1987). Based on these views, the role of education in sustainable development was re-examined in 1992 at the United Nations Earth Summit on Environment and Development in Rio de Janeiro. The concept of education was unanimously linked to sustainable development in ► [Agenda 21](#). Preliminary ideas on Education for sustainable development (hereinafter ESD) are described in chapter "Promoting Education, Public Awareness and Training". This chapter describes four key issues in implementing ESD: (1) improving basic education, (2) reorienting existing education to promote sustainable development, (3) developing public understanding and awareness of sustainability, and (4) educating literate and environmentally conscious citizens (UN 1992). Agenda 21 promoted the debate on the role of education and training in sustainable development and the key role of sustainable development in education and training policy initiatives and actions both nationally and internationally in the coming years. In particular, international political and economic organizations (e.g., United Nations, Organization for Economic Co-operation and Development, Organization of American States) have promoted ESD by recognizing that education is the key to sustainability (McKeown 2002).

In 2000, discussions on the basis of previous publications produced the Millennium Declaration including Millennium Development Goals (MDGs). They drew attention to growing global problems, especially to challenges facing the countries of the southern hemisphere. Key issues were besides others extreme poverty and hunger, gender equality and rights, and children education (UN 2000, 2015b). Gender plays an important role in sustainable development. Gender stereotypes and norms shape the way men and women

think and act. Lifestyle differences and social identities can also affect how individuals act in environmentally relevant situations. Gender inequalities, societal, and power issues are increasingly addressed in the debate on sustainable development. Also, Sustainable Development Goal 5 “Achieve gender equality and empower all women and girls” stresses gender equality stating (UN n.d.): “Gender equality is not only a fundamental human right, but a necessary foundation for a peaceful, prosperous and sustainable world.” In sustainable discussions on the MDGs has been stated that changes in values, lifestyles, and policies worldwide are crucial to achieve a sustainable foundation (Huckle and Wals 2015). Transformative education is seen as a way to promote change in the thinking and action of individuals and cooperation between stakeholders.

The importance of Agenda 21 for education was reaffirmed at the World Summit on Sustainable Development in Johannesburg (2002). This culminated in the proposal of the UN Decade of Education for Sustainable Development for the period 2005–2014 (DESD 2005–2014, ESD Decade) (UN 2002/2004). The Johannesburg Declaration brought together all aspects of sustainable development with the aim of making education a key catalyst for change (Michelsen and Wells 2017). ESD Decade aimed to encourage changes in knowledge, values, and attitudes with the vision of enabling a more sustainable and just society for all (UNESCO 2017a). The change was thought to be achieved by integrating sustainable development values into all areas of learning (UNESCO 2005). According to the UN DSD (2014), “The **vision** of Education for Sustainable

Development (ESD) is a world where everyone has the opportunity to benefit from quality education and learn the values, behaviour and lifestyles required for a sustainable future and for positive societal transformation.” ESD Decade triggered worldwide changes, particularly with regard to the role and understanding of ESD.

Key milestones in ESD culminated in the Bonn Declaration in 2009, which called on the ESD to actively promote gender equality and to create the conditions and strategies to share knowledge and experiences on social change and well-being for women (Michelsen and Wells 2017).

United Nations Conference on Sustainable Development (Rio + 20) launched the Agenda “The Future We Want” to guide development after 2015. It called for the establishment of common global goals to promote sustainable development. During Rio + 20 in 2012, an education working group prepared a paper “The Education We Need for the World We Want” (TEWN) in parallel with the official summit (Huckle and Wals 2015). According to the authors, the causes of the global crisis go beyond neoliberalism and its economic, social, and environmental impacts. They argue that global crisis is also an education crisis. The authors state that there is a need for critical and transformative education that respects human rights and the rights of the community to which people belong, and in particular promotes the right of citizens to participate in decision-making on sustainable development, for example (Huckle and Wals 2015).

The last conference concerning ESD Decade was held in Aichi-Nagoya in 2014. The aim of the declaration called “Global Action Programme” (Global Action Plan) (GAP) is to support and promote the process leading to sustainable development in all fields of education. GAP emphasizes the importance of leadership in the implementation of sustainable development projects in both formal and non-formal education. It calls on all stakeholders, in particular Ministries of Education together with other Ministries and educational institutions involved in education, to jointly promote the creation of knowledge on sustainable development and ESD (Huckle and Wals 2015).

The next milestone was reached in 2015 in discussions based on the Brundtland Report (1987), the Agenda 21 (1992), and the Millennium Development Goals (2000). In the Agenda for Sustainable Development (► [Agenda 2030](#)), 17 Sustainability Development Goals (SDGs) were presented. They apply to both developing and developed countries and cover both the ecological, social and economic dimensions of sustainable development, and the idea of inter- and intragenerational justice. The fourth goal (SDG4) “Quality education” promotes inclusive and high-quality education for all and lifelong learning (United Nations 2021).

Position of ESD in Formal, Non-formal, and Informal Education

ESD has been recognized internationally in three at the World Summit on Sustainable Development: the United Nations Conference on Environment and Development (UNCED) in 1992 in Rio de Janeiro, Brazil; the World Summit on Sustainable Development (WSSD) in 2002 in Johannesburg, South Africa; and the United Nations Conference on Sustainable Development (UNCSD) in Rio de Janeiro, Brazil. Its importance has also been emphasized in other key global agreements, such as the Paris Agreement (Article 12) (UNESCO 2017a).

ESD is part of the quality education included in the concept of lifelong learning. Both formal education (from pre-school to higher education), non-formal education (community education, adult education, and second-chance education), and in-formal learning (involuntary and an inescapable part of daily life learning) (Council of Europe 2021; Lockhart 2016) should be focused on issues of sustainable development. They should also promote sustainable development skills that are relevant to understanding and solving today’s social, economic, and environmental problems. ESD is recognized as a key instrument to achieve the SDGs (UNESCO 2017a).

Relationship Between EE and ESD

Regarding the relationship between EE and ESD, it is important to understand the extent to which they are interrelated and different. The content and pedagogical differences between EE and ESD are based on the country's or region's views on citizen participation and democracy.

Concerning the content dimension, Wals and Kieft (2010) describe three relationships between ESD and EE: (1) EE equals ESD, (2) EE is a part of ESD, and (3) EE and ESD have elements in common but are distinct (Wals and Kieft 2010). According to Hesselink et al. (2000), there is also a fourth relationship, and ESD is the successor to EE.

Two responses within the view of the equal relationship between EE and ESD can be seen. In some countries, EE continues to be developed and taught because people recognize it better than ESD (e.g., the USA). Others use ESD for strategic or practical reasons without changing their EE policy. In the latter case, development has led to the EE of sustainable development (e.g., Taiwan) or the EE of a sustainable society (e.g., Brazil) (Wals and Kieft 2010). When EE would become ESD, EE could lose some of its uniqueness, that is, the notion that humans are part of nature. ESD is more human-centered than EE. Such a development would eventually also impoverish ESD (McKeown and Hopkins 2007).

In some countries, the emergence of ESD has encouraged the reform of EE to become part of ESD (e.g., Vietnam and many Arab countries). The reason for the reform has been the perception that EE focuses too narrowly on environmental protection and natural resource management, as well as nature conservation. So, ESD is needed to increase the socioeconomic, political, and cultural dimensions. The integration of EE and ESD is thought to support the idea that, in addition to ecological sustainability, social considerations could be better taken into account in teaching and learning processes (Wals and Kieft 2010).

In some countries (e.g., The Netherlands, Canada, and Greece), ESD and EE are distinct, albeit partially overlapping. ESD is needed to bring important new dimensions that are not or only lightly addressed by EE (e.g., socioeconomic

and cultural dimensions). When the political, social, cultural, and economic views of EE and ESD are interpreted broadly, the concepts become almost synonymous. The same happens when they are interpreted narrowly with a focus on the environment and ecology (Wals and Kieft 2010).

Many see ESD as the next generation of EE that includes ethics, equity, and new ways of thinking and learning. According to this view, ESD is (Hesselink et al. 2000, p. 15):

- More future-oriented (careful examination of probable and possible futures)
- Critical of the predominant market and consumption driven society
- More sensitive to the different realities that challenge people around the world (sensitive to context)
- More systemic in dealing with complexity
- More community and solidarity oriented (as opposed to individualistic and self-promoting)
- Less concerned with product (behavioral outcomes)
- More concerned with process (creating the right conditions for social learning)
- More open to new ways of thinking and doing
- Preoccupied with linking social, economic, and environmental equity at the local, regional and global level.

Relationships Between ESD and Other Forms of Education

In addition to EE, there are many other forms of education related to the promotion of sustainable development. For example, from the perspective of the environmental dimension, in addition to EE, there is also a need for ► [biodiversity education](#) and climate change education. The socio-cultural dimension in its part includes peace education, global citizenship education, health education, and human rights education. Examples of economic education include Disaster Risk Reduction and the Program of Education for Emergency and Reconstruction (PEER) (Wals and Kieft 2010).

In addition, Global Learning for Sustainable Development (GLSD) is a new form of education with a focus on international sustainable development issues (Anderberg et al. 2008, p. 369). It addresses everyday problems, global processes, and conflicts and supports to understand the relationships between them. In these, all forms of education sustainable development issues can be addressed in an integrative way from multiple perspectives, disciplines and perspectives (Wals and Kieft 2010).

Information Technology Contributing to ESD

Information technology and Internet-based distance education, which allows for reduced costs and increased flexibility in offering materials, make high-quality lectures available to a wider audience (Wals and Kieft 2010). According to Kumpulainen and Mikkola (2015, pp. 24–25), information technology supports community learning in addition to individual learning. It has positive effects also on learners' shared information processing and thinking levels, and the development of ideas (Bowerman 2011). There is a serious problem with the use of the Internet in teaching. It will mainly achieve a globalizing world, leaving many developing countries out of the teaching and learning opportunities it offers. In addition to the digitalization of teaching methods, society is digitalizing. Learning the skills needed in working life develops learners' ability to critically evaluate things, develop new cultures, and innovate thinking and practices (Norrena 2013). Key issues in the development of both digital learning and teaching materials are collaborative and problem-based learning and the learner's independent action.

The Goal, Content, and Pedagogy of ESD

ESD is a holistic transformative education that addresses both the goal of education and learning objectives, content and outcomes, as well as pedagogy and learning environment. The goal of ESD

is to provide learners with information for responsible environmental action by supporting the values, knowledge, multidisciplinary skills, and understanding needed for sustainable environmental management, the promotion of social justice, and the eradication of poverty (Coriddi 2008; UNESCO 2017a). In particular, the ESD aims to promote SDG4 and Global Citizenship Education (GCED), but it is also important for achieving the other 16 SDGs. ESD is also useful in encouraging people to participate in action of sustainable development and to promote social, economic, and political change, as well as to change their own behavior.

ESD aims to develop competence so that individuals are able to look at their own actions taking into account current and future social, cultural, economic, and environmental impacts from a local and global perspective. Individuals should also be empowered to act in a sustainable way in complex situations, which may require them to participate in socio-political processes and change their societies towards sustainable development. In this case, the ability to work with actors with different value systems, as well as the ability to find meaningful compromises when stakeholder goals are conflicting are needed (Dale and Newman 2005).

ESD enables all individuals to contribute to the achievement of SDGs by providing the necessary knowledge and skills so that the individual can understand what the SDGs are pursuing and by developing the individual's environmental awareness to bring about the necessary change (UNESCO 2017a). ESD focuses on processed and traditional fact-based knowledge in order to take into account unpredictable changes in ecological and social systems (Dale and Newman 2005). On the content level, ESD is linked to an idea of universal concepts and human rights applicable to everyone, but at the same time, concrete links to the local circumstances and lifeworlds should also be taken into account (Biesta 2009). Incorporation of ESD into teaching-studying-learning processes contributes to the understanding of various global issues related to sustainable development, for example, climate change, poverty, human rights, globalization, equality issues,

professional ethics, and environmental challenges. Combining theory and practice supports students' ability to connect with the real world and encourages them to think of themselves as global citizens. This can be fostered a sense of global social responsibility (Leal Filho et al. 2018).

ESD is a holistic and transformative education. It does not only integrate content into the curriculum but also creates interactive learner-centered teaching and learning environments (Ghemawat 2017; UNESCO 2017a). The origin of ESD is problem-based education and the combination of inter- and transdisciplinary approach (Dale and Newman 2005). So, ESD calls for action-oriented pedagogy that supports self-directed and participatory learning, cooperation and collaboration, and formal, non-formal, and informal learning (UNESCO 2017a). The development of students' action strategies based on sound expertise, judgment, and problem-solving skills are thus in the core of teaching and learning processes (German Geographical Society 2012). According to Meyer (2006), cognitive, instrumental, social-communicative, and active learning are crucial in ESD.

Regarding pedagogy and the learning dimension, Wals and Kieft (2010) state that the concept of "education" in ESD can be understood in different ways depending on how much opportunity there is to participate, work independently, and think. When opportunities are scarce, ESD places more emphasis on teaching methods and knowledge transfer. Abundant opportunities, on the other hand, increase participation, independent work and thinking, and knowledge creation. The latter versions of ESD require alternative teaching and learning strategies that develop also new skills and competencies. Education should pay more attention to the qualities needed to promote sustainable development. The term "sustainable development skills" refers to the competencies needed to meet the challenges of sustainable development (Wals and Kieft 2010).

ESD Competencies

Competence describes the attitudes that individuals need in a given operating environment and

self-organization in a variety of complex contexts and situations (Rieckmann 2011). In order for individuals to be able to participate in sustainability issues, education needs to address sustainable development issues and promote sustainable development key competencies (UNESCO 2005). Key competences refer to transversal, multifunctional, and context-overall competencies that are considered particularly important in achieving societal goals that are important for a defined normative framework (e.g., sustainability) and that are important for all individuals (Rieckmann 2012). The ESD aims to develop key competencies that enable individuals to participate in sociopolitical processes and thus contribute to the transformation of society towards sustainable development (de Haan 2006). The most relevant key competencies are those for systemic thinking and handling of complexity, anticipatory thinking, and critical thinking (Rieckmann 2012).

ESD Implementation Challenges

According to Wals and Kieft (2010), despite progress, there are still a number of problems with the implementation of ESD. The following things are challenging (Wals and Kieft 2010, pp. 8–9):

- Generating financial support earmarked for ESD
- Reforming and re-orienting educational contents, methodology, and curricula to address ESD-based skills, knowledge, and values
- Facilitating and strengthening networking between schools, educational institutions/organizations, and other partners involved in ESD at national and international levels
- Putting more emphasis on non-formal and informal education
- Lack of ESD tools and materials
- Improving legal and regulatory measures that support ESD
- Designing ESD-professional development programs and ESD-pre-service training programs for teachers, educators, administrators, and leaders

- Establishing for deepening a national ESD strategy and developing commitment towards it
- Exchanging good examples, and sharing knowledge and experience
- Promoting ESD research, monitoring, evaluation, and dissemination
- Creating linkages between ESD and EE as well as with other forms of educations.

Ways Forward

According to Wals and Kieft (2010), the following actions are needed:

- 1) Awareness and understanding of the meaning and application of ESD should be raised through the media, especially among young people around the world.
- 2) Reorientation of curricula, teaching, and learning is necessary to strengthen sustainable development capacities (e.g., understanding complexity, perceiving connections and interdependencies, participating in democratic decision-making and processes, questioning routines).
- 3) The professional capacity of staff at schools, universities, and workplaces (e.g., concerning corporate social responsibility, CSR) should be increased.
- 4) Education on the relationship between ESD and the environment and cooperation between ESD and other forms of education should be increased.
- 5) In particular, topical ESD-promoting materials should be developed. Creating easy-to-use ESD information sharing platforms would facilitate the use of ESD resources.
- 6) International and regional cooperation should be supported.

Summary

ESD aims to find sustainable solutions to local and global problems through a transformative perspective. The core ideas of ESD are social

justice and cultural diversity. Today, the crucial goal is to learn to live sustainably. Achieving a sustainable foundation requires changes in values, lifestyles, and policies globally (Huckle and Wals 2015). This again requires education systems, educational institutions, and educators with a willingness to tackle sustainability problems and the ability to respond to them.

A useful way to promote thinking and behavioral change in individuals and enable cooperation between actors is transformative education. Its objective is to foster individuals' critical thinking and support them in changing their own reality. According to Sustainable Development Goal 5 (UN n.d.), education should address social and power aspects as well as gender inequality to reduce gender inequality and improve human well-being. Gender inequalities do not in themselves cause environmental problems, for example, climate change, the loss of biodiversity, or social problems. However, they affect the thinking and action of individuals and communities worldwide. Climate change and other environmental issues can best be addressed through cooperation between stakeholders based on scientific knowledge. Thus improving women's education and participation in society is important not only for human being but also for the planet.

Education for Sustainable Development (= ESD)

Definition

ESD is an interdisciplinary learning perspective. ESD combines aspects of environmental education and development assistance. Economic, ecological, cultural, political, and social aspects in formal and informal learning environments are in focus.

The aim of BNE is to give individuals the opportunity to live actively and self-organized in terms of local, national, and global dimensions, as well as to consider the short-term and persistent effects of their own activities on the environment. This includes emotional, rational, and action-oriented components as well as the acquisition of judgment in different life situations. Almost every topic can be one of ESD, if it is focused with that interdisciplinary ESD view. This diversity requires a well-organized structure and focus for concrete teaching situations.

History of ESD

Over the last 20 years, the perspective of ESD has been established. It is now a key element of qualitative education and covers a wide range of educational areas, including social, economic, cultural, political, and environmental aspects. The starting point was the global political debate on the management and consumption of natural resources. Global environmental issues such as natural resource overuse or misuse, climate change, biodiversity distinctions, and lack of

knowledge about the main ideas of sustainable use were obvious. On the other side also, developmental assistance realized that environmental protection is one part of sustainable development processes. Nowadays it is visible that the earth has natural limits that must be taken into account (Hagedorn et al. 2019).

Back in 1987, the Brundtland Commission formulated the concept of sustainable development. It was about satisfying the requirements of the current world population and at the same time not jeopardizing the possibilities of coming generations. Today's natural state should at least be maintained, so that future generations have the same freedom to decide on their livelihood. The perspectives should remain the same for all generations.

In 1992, for the first time, Rio de Janeiro's final document focused on education alongside political and economic measures. The guiding principle should be sustainable development for humanity in the twenty-first century. Agenda 21, the environmental and development-oriented policy action program for global sustainable development, was signed by 170 governments. This can be seen as starting point for ESD. Chapter 36 of Agenda 21 (1992) mentions that the United Nations will "promote high quality education, public awareness and vocational education and training." This was the first time that sustainable development and education were on an official agenda.

The UN Decade of Education for Sustainable Development (2005–2014) aimed to anchor ESD in formal and informal education systems. This was a very ambitious goal. New networks and knowledge have been built to jointly address global issues such as climate change, poverty, and overuse of natural resources. During this time, ideas for sustainable development goals were developed, discussed, and finally formulated (Vey 2015). This period has also shown that it is very important to anchor ESD on the ground and that, in particular, young people and local communities are central to achieving the goal of a well-connected and informed society. It is necessary to improve the knowledge about sustainable development among teenagers (Holfelder 2016) as they are the ones to decide in future.

The next important political step was the 2030 Agenda for Sustainable Development. The United Nations agreed on 17 Sustainable Development Goals (SDGs). The five core messages People, Planet, Prosperity, Peace, and Partnership, the so-called 5Ps, are preceded as guiding principles. The SDGs consist of (1) no poverty, (2) no hunger, (3) good health and well-being, (4) high quality education, (5) gender equality, (6) clean water and sanitation, (7) affordable values and clean energy, (8) decent work and economic growth, (9) industry, innovation, and infrastructure, (10) reducing inequality, (11) sustainable cities and towns, (12) responsible consumption and production, (13) Climate action, (14) underwater life, (15) land life, (16) peace, justice and strong institutions, and (17) partnership for goals. Their image as shown in Fig. 1 can be found worldwide.

These goals were not only developed for a certain part of the world. They apply to all nations, including the industrialized countries. Therefore they all have development tasks. SDG No. 4, for example, should guarantee equitable, qualitative,

and comprehensive education for all people by 2030 and encourage permanent learning opportunities for all members of the society. Today in Germany educational success depends more on social background than in most other OECD countries (Baader and Freytag 2017). With regard to Agenda 2030 this must be critically questioned and changed.

ESD at Present

The concept of ESD has been legitimized by many decisions – from the United Nations to individual states and provincial governments. It is an open framework in which sustainable, competence-oriented education can be realized. ESD answers the question of what students should and can learn today. It can be realized, from kindergarten and elementary school (Stolltenberg 2009) to vocational college, as many examples show. Indicators to measure the influence of ESD in Germany have been developed and discussed (Michelsen et al. 2011).

Education for Sustainable Environment, Fig. 1 Source: UN Communication Material. <https://www.un.org/sustainabledevelopment/news/communications-material/>. 8.6.2019

ESD makes “railings” for sustainable development. The rule of constant natural capital and the rule of sustainable management become tangible in concepts such as efficiency, sufficiency, and resilience. This shows that strategies other than higher, faster, and more personal income are welcomed and considered. It is amazing what different types of resource use come into play. Shared working positions, the growing share of cars and bicycles are examples of intelligent dual use of resources. They are commonplace today, at least in larger modern cities. Beside necessary political decisions people are starting to think about their personal CO₂ production, and communities want to reduce their negative input or think about strategies to become more environmentally friendly. People’s awareness of sustainable development goals is increasingly coming to the fore, but on the other hand it is becoming more difficult to understand the complexity of individual decisions. What is needed, however, is the step toward awareness that this change is necessary and possible.

ESD activities focus on strengths and competences that promote sustainable development. This should help to find new answers to urgent actual problems. Instead of talking about threat scenarios, the ESD learning perspective emphasizes competences that should be promoted among participants in ESD education activities.

The focus is on key competences of the cognitive, socioemotional, and acting domain (Bormann and Haan 2008; Schreiber and Siegel 2016). The realignment of educational and learning processes means that everyone worldwide should have the opportunity to acquire appropriate knowledge and skills and moral and ethical bases for decision-making in their respective situation. These should enable humans to contribute to a sustainable future. Education and learning in all agendas, programs and activities needs to be strengthened to promote sustainable development. This includes lifelong learning activities (UNESCO 2014). They start at an early age, as small children are in a very sensitive phase of appropriating the world, and they last their entire life into old age. The UNESCO states that

necessary skills include system thinking, critical thinking, self-esteem, predictive skills, normative skills, strategic skills, collaboration skills, and integrated problem-solving skills (UNESCO 2017).

The basic understanding of ESD is that teachers and learners create knowledge together. This co-constructivist path is promoted through methods that support participatory, constructive, explorative, reflective, or discursive learning. It would be good if ESD will be more than a one-day activity, or at least integrated with other educational offerings. Learners should not be indoctrinated, but should be able to distinguish between approaches as described in the “Beutelsbacher Consensus” (Frech and Richter 2017). Education has to be thought of by the resource-oriented side and not by the fault-oriented side.

ESD deals with very different topics. There is a wide field of neighboring perspectives and concepts. These include Cultural Studies (Molderez and Ceulemans 2018), Peace Studies as well as Poverty Reduction Studies. Greater prosperity is a prerequisite in many poorer countries in order to achieve fairer conditions worldwide. Cultural Diversity Studies, Ecosystem Approaches (Adom̄ent and Leicht 2011), Democracy and Governance (Pāsnikowska-Lukaszuk and Wójcicka-Migasiuk 2017), Environmental Protection (Thomas et al. 2019), Natural Resource Management or Corporate Social Responsibility (Sodiq et al. 2019), and Production/Consumption Patterns (Puma et al. 2015) are included in many questions of ESD.

In school surveys, audits, and surveys, learners can acquire interdisciplinary knowledge and integrate new perspectives. Active and intrinsic learning should be encouraged. In future workshops, learners will be able to express their interests, knowledge, and commitment to shaping their living environment. If a larger political reference framework is chosen – such as, for example, federal or international politics, learners can simulate contradictory goals in plan or role-play games and train participation in collective decision-making processes. In

simulations they can actively experiment and proactively analyze and evaluate future developments. If possible, real projects should be involved. Last but not least, well-thought-out educational experts are in demand.

Today ESD is involved in formal and informal educational systems in many European countries (Bormann et al. 2016; Dlouhá et al. 2017; Stein et al. 2016; Takala et al. 2019). Educational activities work together and, in the best case a good integration of practice and theory takes place. It has reached a new quality to include non-formal education on a broad basis as part of the educational process. Non-formal education has a very high thematic and qualitative diversity. Therefore, there is, for example, in North Rhine-Westphalia in Germany, the ESD agency, which certifies educational offers, and so-called ESD centers, which network different education systems and establish qualitative education offers.

Finally, it should be possible to conserve natural resources and to distribute resources more equitably to all people and regions of the world than is currently the case. Hopefully this objective will be achieved without losing economic wealth, but with a wide range of alternatives to unsustainable use of natural and human resources.

Summary

ESD as an interdisciplinary learning perspective is intended to give the individual the opportunity to actively contribute to a world for all people, living together in partnership peace and prosperity, with a focus on the whole planet. Therefore, high-quality education for all age groups should be possible worldwide. A particular focus is on the competencies that must be developed through a variety of educational opportunities.

Effectiveness

Carmela Gulluscio
Unitelma Sapienza University of Rome, Rome,

Synonyms

Efficacy; Helpfulness; Usefulness

Definition

Effectiveness can be defined as the aptitude to fulfill the desired purpose (Gulluscio 2014a).

It is typically represented through the ratio between *results* and *objectives*.

The latter can be understood as *outputs* or *outcomes*.

The outputs can be identified as the simple count of the number of goods or services supplied. Examples of outputs are the number of goods or services purchased, the number of hospitalization days for health care organizations, the number of lessons taught by universities, etc.

The outcome is a more complex concept, as it represents the effects that the goods or services provided have produced on satisfying the users' needs. Examples of outcomes are the effects of health care services on the improvement of patients' health or the effects of the lessons given on students learning.

It is easy to understand that, while it is quite simple to quantitatively measure the output, this is much more complicated for the outcome. The latter is usually estimated using a complex system of indicators aimed at judging the effects produced on final users.

According to Pavan and Reginato (2004), effectiveness can be expressed as:

- *Internal effectiveness*, i.e., the ratio between results and objectives analyzed as “output.” This result gives information about the aptitude

to succeed in a specific goal, but no information is provided about the aptitude to meet the expectations of external stakeholders.

- *External effectiveness* or *social effectiveness*, i.e., the ratio between results and objectives analyzed as “outcome.” This result explains whether the organization can satisfy the needs of external stakeholders.

Introduction

The concept of effectiveness presented in this entry refers to the different meanings of the term used in the sustainability management literature. Within this body of literature, the concept of sustainable development has progressively developed over time (Young and Tilley 2006, p. 403).

The first stage of attention to sustainable development emerged in the 1960s and 1970s when many corporations started giving attention to pollution control, building solutions aimed at reducing their impact on the natural environment.

In the 1980s the Brundtland Report (WCED 1987) stimulated the beginning of attention toward the concept of “sustainable development.”

In the 1990s the concept of “triple bottom line” (Elkington 1997) emerged.

During the 1980s and the 1990s, a second stage of attention toward sustainability-related issues emerged: Many companies understood the potential usefulness of environmental management practices in terms of cost savings. During this second stage of attention toward sustainability issues, companies mainly focused on the search for *efficiency* and *competitive advantage*, with the purpose of “doing more with less.” In this context, companies considered *eco-efficiency* as a win-win solution, i.e., as a solution enabling companies to achieve at the same time the goals of economic growth and environmental protection (Holliday et al. 2002).

The attention toward “sustainable development” and “triple bottom line” broadened the interpretation of corporate responsibility, understood not only under the economic aspect but also the natural (environmental) and social aspect. The

attention toward these three aspects of corporate responsibility recently is often referred to as *corporate sustainability*.

At the end of the twentieth century, the third stage of attention toward sustainability issues arose, with the emergence of the *eco-effectiveness* concept. The basic idea was that business practices cannot be limited to pollution control and eco-efficiency but must go further, including also business attention toward the restoration and enhancement of the environment. The inadequacy of eco-efficiency as a guiding criterion for business activity was underlined by various scholars (see Day 1998; Gray and Bebbington 2000; Walley and Whitehead 1994; Welford 1997). About sustainability accounting, the inadequacy of eco-efficiency as the main guiding criterion has been underlined by Gray and Bebbington (2000), who argue that most of the solutions related to eco-efficiency generated by firms are business centered rather than environment or sustainability centered.

Different Perspectives of Effectiveness

Starting from the limits of eco-efficiency to achieve sustainability objectives, McDonough and Braungart (1998) introduced the concept of “eco-effectiveness,” aiming at allowing organizations to be at the same time efficient, life sustaining, restorative, and regenerative. This was a significant innovation on the path to sustainability, shifting organizations to change their minds from the old “cradle-to-grave approach” to a new “cradle-to-cradle approach,” in which the principles of reduce, reuse, and recycle are applied to waste management.

Socio-effectiveness can be understood as the positive impact of an organization’s activities on society (Young and Tilley 2006, p. 405).

The emergence of effectiveness as a guiding principle for sustainability-oriented practices finds a milestone in two main publications:

- a) Dyllick and Hockerts (2002)
- b) McDonough and Braungart (2002)

According to Dyllick and Hockerts (2002), sustainable organizations cannot be limited to

being eco- and socio-efficient; they should also pursue the objectives of eco- and socio-effectiveness, sufficiency, and ecological equity. The latter is sometimes referred to as “ecological justice.”

There is a strong relationship between the concepts of effectiveness, efficiency, and equity. In a broad sense, effectiveness is the ability to achieve the desired purpose. Efficiency can be understood as: (a) the ability to minimize the resources used in comparison to the same result achieved or (b) the ability to maximize the result being equal the means employed (Gulluscio 2014b). Equity refers to the existence of equal rights for all the people or social groups for the satisfaction of their needs, both in a given moment and for different generations. In this sense, “ecological equity” refers to equal rights for all people or social groups to environmental resources (Young and Tilley 2006).

According to the authors, three main perspectives are to be considered within corporate sustainability, that is:

- 1) the *business* perspective
- 2) the *natural* perspective
- 3) the *societal* perspective

In the *business perspective* (i.e., considering business/economic sustainability), two main dimensions are considered: (a) eco-efficiency and (b) socio-efficiency. The most relevant criterion for judging the achievement of corporate sustainability is the organization’s *efficient use of natural capital*. This is an *eco-efficiency* measure usually determined as the economic value added by the organization concerning its aggregated ecological impact (Dyllick and Hockerts 2002, p. 136; Schaltegger and Sturm 1990, 1992, 1998). It refers to an organization’s efficient use of natural resources and is usually determined as the economic value added related to the organization’s aggregate ecological impact (Young and Tilley 2006, p. 408). “Eco-efficiency is reached by the delivery of competitively-priced goods and services that satisfy human needs and bring quality of life, while progressively reducing ecological impacts and resource intensity throughout the life cycle, to a

level at least in line with the Earth's estimated carrying capacity" (Robins (Ed.) 1993, p. 8).

The main indicators for eco-efficiency currently used by firms include waste/pollution intensity and energy, water, and resource efficiency.

In the business perspective, another relevant criterion for judging the achievement of corporate sustainability is *socio-efficiency*, i.e., the relation between an organization's value added and its social impact (Dyllick and Hockerts 2002; Hockerts 1996, 1999; Figge and Hahn 2001). "It requires the minimization of negative impacts, such as accidents at work and the maximization of positive social impacts, such as training and health benefits" (Young and Tilley 2006, p. 408).

In the *natural perspective* (i.e., considering natural sustainability), two main dimensions are considered: (a) eco-effectiveness and (b) sufficiency. Organizations operating close to or beyond the environment's carrying capacity can never come to be fully sustainable. In this perspective, ecological sustainability must deal not only with relative improvements but also with absolute thresholds. Therefore, the main issue to be considered is not eco-efficiency but *eco-effectiveness*. The latter term "is used in different ways. It was used by Schaltegger and Sturm (1990, 1992, 1998) in the sense of technical effectiveness, which complements the economic value orientation to eco-efficiency. Braungart and McDonough (Braungart 1994; Braungart and McDonough 1998; MBCD 2001) on the other hand use the term in clear opposition to eco-efficiency: 'Long-term prosperity depends not only on the efficiency of a fundamentally destructive system, but on the effectiveness of processes designed to be healthy and renewable in the first place. Eco-effectiveness celebrates the abundance and fecundity of natural systems, and structures itself around goals that target 100 percent sustaining solutions (MBCD 2001)'" (Dyllick and Hockerts 2002, p. 136).

Within the natural perspective, another criterion usually employed is *sufficiency*, mainly interpreted as "an issue of individual choice rather than a single firm's responsibility. [...] Both eco-effectiveness and sufficiency are criteria looking at ecological sustainability as their main goal with business and

society as the main drivers for producing greater environmental good" (Dyllick and Hockerts 2002, p. 137). It emerges from the integration of environmental sustainability and social sustainability (Hockerts 1999, p. 6). It "refers to the actions of individual consumers to make responsible choices right through to consumers collectively boycotting or subverting corporate branding and marketing strategies that are believed to be environmentally harmful" (Young and Tilley 2006, p. 408). The following considerations can explain the concept of sufficiency: "Must we cut back? Since the late 1980s, the 'deep green' response to 'green consumerism' has been not to consume differently but to consume less. [...] Companies determined to remain at the cutting edge should be applying some form of 'need test' to their products or services [...] [which] provides an initial set of questions to get the process started" (Sustainability 1995, pp. 10–11).

In the *societal perspective* (i.e., considering social sustainability), two main criteria are considered: (a) ecological equity and (b) socio-effectiveness. *Ecological equity* "stands at the nexus of the relationship between the management of natural capital and social sustainability. While current generations consume large parts of the earth's natural capital, the bulk of damage is likely to be borne by future generations" (Dyllick and Hockerts 2002, p. 138).

Socio-effectiveness examines the organization's "conduct not on a relative scale but rather in relation to the absolute positive social impact a firm could reasonably have achieved." It "refers to the assessment of a firm's absolute social performance. Are a company's products accessible and therefore benefiting all or just an elite few?" (Young and Tilley 2006, p. 408).

An overview of the three mentioned dimensions of corporate sustainability and the six connected criteria (including different types of effectiveness) is presented in Fig. 1.

McDonough and Braungart (2002) apply a triangular model similar to that of Dyllick and Hockerts (2002), introducing the concept of *triple top line thinking* which shifts the attention toward the beginning of the design process. In this model, there are three dimensions constantly connected:

Effectiveness,

Fig. 1 Three dimensions and six criteria of corporate sustainability. (Source: Dyllick and Hockerts 2002, p. 138)

Effectiveness, Fig. 2 Fractal triangle. (Source: Braungart and McDonough 2002, p. 253)

ecology, economy, and equity. They are represented in a fractal triangle (see Fig. 2) showing that every product is produced and used in an interconnected world. “Each of these schools of thought – capitalism, socialism, ecologism – was inspired by a genuine desire to improve the human condition. But taken to extremes – reduced to isms – the stances they inspired can neglect factors crucial to long-term success. Even ecological concern, stretched to an ism, can neglect social, cultural, and economic interests to the detriment of the whole system. In short, holding one of these concerns *the* ultimate goal often puts economy, ecology and equity at cross-purposes. So does measuring your performance by how well you are managing the bottom line liabilities that arise from these seemingly conflicting interests. Triple

top line thinkers, rather than trying to limit the influence of one or the other of these value systems, discover opportunities in honoring the needs of all three” (McDonough and Braungart 2002, p. 254).

Key Issues

Corporate sustainability indicators include three main areas: (a) business, (b) natural, and (c) societal. Effectiveness is a measure recurring in these three dimensions but in different forms. According to the “Sustainability Triangle” (Fig. 3) proposed by Schaltegger ([forthcoming](#) in this Encyclopedia), effectiveness can be examined under an economic (i.e., business), ecological (i.e., natural), and social (i.e., societal) perspective. The integration of these three areas with of efficiency and effectiveness measures leads to a multidimensional perspective about sustainability management, as Fig. 3 displays.

Summary

Sustainability management is moving in the direction of integrating different perspectives (i.e., the business/economic, the natural/

Effectiveness, Fig. 3 The sustainability triangle of corporate sustainability management. (Source: Schaltegger and Burritt 2005, 189)

ecological, and the societal/social perspectives) and different dimensions (i.e., efficiency and effectiveness). This seems to be the most promising way to capture all relevant aspects of sustainability management and to move toward a multidimensional approach to sustainability issues.

EMAS: Eco-Management and Audit Scheme

Janusz Reichel

Faculty of Management, University of Lodz,
Lodz, Poland

Synonyms

Environmental management standard; Environmental management system; Environmental management system requirements

Definition

Eco-Management and Audit Scheme (EMAS) is the initiative proposed by the European Commission that presents guidelines and organizational infrastructure to allow organizations from different sectors to voluntarily participate in the scheme by the implementation of environmental management systems and demonstrate their advances through publicly available periodic environmental statements with information on their compliance with applicable legal requirements and their environmental performance (Regulation 2009). EMAS focuses on continuous improvements in the environmental performance of an organization by the establishment and implementation of environmental policy and management of their environmental aspects, the periodic evaluation of the performance of such system, and the provision of information on environmental performance to public opinion.

Voluntary Eco-Management and Audit Scheme

Eco-Management and Audit Scheme (EMAS) is the initiative of European Union to present guidelines and organizational infrastructure that will allow organizations from different sectors to implement Environmental Management System. The European Commission developed and

launched EMAS to enable organizations “to assess, report, and try to improve their environmental performance” (Laskurain et al. 2017, p. 7). The scheme is open to any type of organization from different sectors and countries, even from outside the European Union. As the standard for the Environmental Management System EMAS can contribute to sustainable development offering organizations good management practices to follow, and its implementation can be a manifestation of social responsibility. This kind of initiative belongs to the so-called soft policy instruments or voluntary instruments.

The objective of EMAS, as the legal regulation that introduced it states: “is to promote continuous improvements in the environmental performance of organisations by the establishment and implementation of environmental management systems by organisations, the systematic, objective and periodic evaluation of the performance of such systems” (Regulation 2009). In general, EMAS can help “to evaluate, report, and improve their environmental performance” (European Commission EMAS 2020).

Member states are responsible to organize functioning of the scheme. This means establishment of the Competent Body and the country EMAS register. “Competent Bodies shall establish procedures for the registration of organisations” (Regulation 2009). The organization may apply for one registration for all of its sites or only for some of those sites. The register should include information on environmental statement of organization and where it can be obtained. The information should be updated on a monthly basis. “The register shall be publicly available on a website” (Regulation 2009).

There were three important stages in the EMAS history. The first European certifiable environmental management scheme (EMAS I) was introduced by the Regulation 1836/93 in July 1993. Then in 2001 the revised Regulation (EC) No 761/2001 (EMAS II) appeared and finally Regulation (EC) No 1221/2009 (EMAS III) came into effect on 11 January 2010 (European Commission EMAS Publications 2020). The EMAS I was focused on the manufacturing industry only. “In 2001, EMAS

was revised to integrate ISO 14001 and to allow participation by all economic sectors. The focal point of the revision in 2010 was administrative relief for small- and medium-sized enterprises. Furthermore, the revision made it possible for sites outside the EU to participate” (Myszczyzyn 2017, p. 169).

“In 2017 Annexes I, II and III of the EMAS Regulation were amended to include the changes associated with the revision of the ISO 14001:2015 standard” (European Commission EMAS Publications 2020). EMAS III reference to the ISO 14001 requirements can be explained by the will to make EMAS more recognizable by companies from outside European Union as ISO 14001 is globally accepted standard.

EMAS Versus ISO 14001

EMAS refers to the standard proposed in ISO 14001 but add some new elements. The comparison between the two standards shows their deep similarity (see for example the comparison of the ISO 14001:2015 and the EMAS III in: Laskurain et al. 2017, p. 7). For the description of the functioning of ISO 14001 Environmental Management System please follow the link: ISO 14001.

EMAS adds five important elements above the ISO 14001 requirements:

- “Constant improvement of pro-environmental action by the necessity to renew the registration, to update the environmental statement and a continuous setting out of new environmental objectives” (Myszczyzyn 2017, p. 169).
- An initial environmental review is required in the process of implementation of the system (Regulation 2009).
- “Compliance with the legislation on the environmental protection guaranteed by the participation of government authorities in the system.
- Universal access of public opinion through open publications of environmental

statements, environmental reports” (Myszczyzyn 2017, p. 169).

- “Active involvement of employees in organizations and appropriate training” (Regulation 2009).

The annual statement of the registrant measuring should demonstrate progress against a number of key indicators. Membership in the initiative “can be suspended if progress is not deemed sufficient” (Whitford and Provost 2019, p. 34).

As the ISO 14001 presents the requirements for the environmental management system, it does not require to achieve certain levels of environmental performance (e.g., emission standards, indicators of resources used, or any other achievements levels). In the latest version of EMAS III “the need to establish a set of core indicators of environmental performance” is emphasized (Laskurain et al. 2017, p. 10).

In this light the choice between the ISO 14001 and EMAS is not a choice between two equivalent solutions. EMAS requires an initial environmental review, an annual statement and membership in EMAS can be suspended (Whitford and Provost 2019, p. 34). Because of the above, the EMAS can be perceived as more strict EMS than that offered by the ISO 14001 requirements. “ISO 14001 has requirements that are easier for many firms to meet than those of EMAS” (Whitford and Provost 2019, p. 35). That is one of the reasons why the winning EMS on the market is the ISO 14001. In recent years, companies have shown more preference for – in some sense – the less ambitious ISO 14001 standard.

EMAS Register

EMAS register statistics show organizations and sites that take part in the scheme. There are many differences between the levels of engagement in the particular Member Country. Most of the organizations registered come from: Austria, Belgium, Germany, Spain, Greece, Italy, and Poland. In September/October 2019 there were 3694

organizations and 12,664 sites registered (EMAS register 2020).

Regulation put the responsibility to promote EMAS on Member States that required them to “develop and implement specific measures aimed at greater participation in EMAS by organisations, in particular small organisations” (Regulation 2009). EMAS different popularity in particular European countries can be a result of different levels of engagement of public sector (government) in promoting it. In general, this engagement is crucial for the scheme development. The support of the government is crucial “to produce a stable pattern of incremental adoption over time” (Whitford and Provost 2019, p. 30). In other cases, implementation of ISO 14001 standard can be a good enough alternative for many organizations on the market.

Summary

Eco-Management and Audit Scheme (EMAS) is the initiative of the European Commission. It was created to enable voluntary participation of organizations in the scheme by the implementation of an environmental management system. EMAS as other environmental management systems (e.g., based on ISO 14001 standard) focuses on continuous improvements in the environmental performance. In order to implement the system, an organization needs to establish and implement environmental policy and manage their environmental aspects. This should be supported by the periodic evaluation of the performance of such system and the provision of information on environmental performance to public opinion. EMAS adds some crucial elements above the requirements presented by ISO 14001 standard. They include: the necessity to publish the environmental statement, making an initial environmental review, and creating opportunities to actively involve employees in organizations. In recent years, companies have shown more preference for ISO 14001 standard. Currently (in September/October 2019), there are 3694 organizations and 12,664 sites registered. Most of the organizations

come from: Austria, Belgium, Germany, Spain, Greece, Italy, and Poland.

Embedded Corporate Social Responsibility

- [Embedded CSR](#)

Embedded CSR

Suvi Hirvonen-Ere
Department of Information and Service
Management, School of Business, Aalto
University, Espoo, Finland

Synonyms

Embedded corporate social responsibility;
New-generation CSR

Definition/Description

Embedded corporate social responsibility (embedded CSR) "...involves an organization's core competencies and integrates CSR within a firm's strategy, routines, and operations, and therefore affects all employees" instead of a peripheral CSR based on philanthropy and volunteering (Aguinis and Glavas 2013, p. 314). The peripheral CSR has similarity with the traditional CSR based on donations by charity organizations, whereas "the new-generation CSR appears when corporations embed CSR activities into their core business model, aim to achieve inclusive market development as well as provide solutions that help the bottom of the pyramid (BOP) while advancing their commercial and financial profitability" (Abdelhalim and Eldin 2019, p. 776).

What Do We Speak About When We Speak About Embedded CSR?

The definition of the corporate social responsibility by the European Commission in their Green Paper promoting a European framework for corporate social responsibility is "A concept through which the company voluntarily integrates the social and environmental dimensions in its business operations and in its relations with stakeholders" (COM 2001 366). Thus, there are

economic, environmental, and social dimensions. The term CSR addresses the obligations of an organization in a manner that benefits the society (Jamali and Neville 2011; Snider et al. 2003).

Even though literature on corporate social responsibility existed, a uniform definition for the term had not been created; rather, "parallel and sometimes confusing universes exist" (Waddock 2004 p. 5). This confusion motivated Aguinis and Glavas to divide CSR into the embedded and peripheral CSR to bring clarity to the term. They define embedded CSR as an approach that "...involves an organization's core competencies and integrates CSR within a firm's strategy, routines, and operations, and therefore affects all employees" (Aguinis and Glavas 2013, p. 314).

Whereas embedded CSR involves the entire organization, peripheral CSR means an approach where the corporate social responsibility "...is not integrated into an organization's strategy, routines and operations (e.g. philanthropy, volunteering)" and is and therefore perceived as not genuine with potentiality to cause negative perception by employees and consumers (Aguinis and Glavas 2013, p. 314).

Their definition is an acknowledged one; however, Smith and Bartunek (2013) have noted that philanthropy and volunteering also bring many benefits, such as strengthening company values, providing it a license to operate, developing employee and team engagement, and promoting the company brand, and for these reasons, they "are embedded almost by definition" (Smith and Bartunek 2013, p. 339).

As an additional note, an angle to the embedded CSR definition is of educational nature. There, the question is how CSR-related topics are taught in management schools; are they taught as "either specific CSR subjects (stand-alone CSR subjects) or as part of various subjects on the academic curriculum (embedded CSR subjects)" (Setó-Pamies et al. 2015)? In that context, embedded CSR refers to subjects that are rather added on top of another subject taught in a business school, management school, or university.

Why Does Embedded CSR Matter?

The European Commission has determined the goal for CSR as “maximizing the creation of shared value for their owners/shareholders and for their other stakeholders and society at large as well as identifying, preventing and mitigating their possible adverse impacts” (European Commission 2019, p. 3).

In addition to these, companies consider CSR attractive due to the competitive advantage it brings as it generates “favorable stakeholder attitudes and better support behaviors (e.g. purchase, seeking employment, investing in the company), but also, over the long run, build corporate image, strengthen stakeholder–company relationships, and enhance stakeholders’ advocacy behaviors” (Du et al. 2010). In addition, a company can attain a positive impact due to a socially responsible brand influence to their stakeholder engagement (Greening and Turban 2000; Carlini et al. 2019).

When company values, policies, and practices are determined and redetermined on a continuous basis, “learning takes place as CSR is embedded in business processes, and that once it has been integrated, in turn, it generates innovative practices, and finally, competitiveness” (Vilanova et al. 2009).

In addition to corporations and other large companies that are often the focal point when speaking about CSR, small- and medium-sized companies are also interested in the competitive advantage CSR could bring to them. Therefore, even though the CSR-related costs are more challenging for the small- and medium-sized companies than for corporations to carry, “CSR must not be considered as an ad hoc expense, rather it is integrated into company’s core business activities in such a way that it positively affects the company’s performance and its competitiveness by enhancing the developmental potential and reducing the risk profile” (Morsing and Perrini 2009, p. 6).

Thus, embedding CSR into an organization comprises integrating CSR into a company in all relevant management levels and having an impact to the company employees, with the aim to bring

the desired benefits, such as competitive advantage, caused by an enhanced brand image, employee engagement, and stakeholder engagement, to the organization that applies embedded CSR.

How to Integrate, or Embed, CSR into an Organization?

Various ways have been proposed to integrate, or embed, CSR into an organization.

Implementing the ISO standards is one of those ways. The ISO 9000 quality system standards (International Organization for Standardization 2015) could offer “a structural and infrastructural platform for organizations to develop and adopt corporate social responsibility (CSR),” whereas the ISO 26000 social responsibility standard could “facilitate a shift from customer focus to stakeholder focus hence creating a business-to-society orientation in organizations” (Castka and Balzarova 2008). The most recent version of the social responsibility standard is ISO 26000:2020 (International Organization for Standardization 2020). Valmohammadi (2014) found remarkable relations between CSR practices and the performance of the organizations and concluded that “community involvement and development plays an important role in enhancing organizational performance of organizations” (Valmohammadi 2014).

Even though utilization of the standard can cause positive impacts in the organizational practice and lead to an increased organizational performance (Valmohammadi 2014), companies may use the standard to signal their social responsibility as more embedded than the actual practice in the given organization and thus cause a false signal of the level of the integration (Moratis 2018).

Diane Swanson has proposed an organizing principle termed “discovery leadership” to reshape the management practice, to renew education in the field of management, and to emphasize the importance of CSR by the voice from the top from the management perspective (Swanson 1999, 2014).

Utilization of existing ways, such as business contracts, in an expanded manner could be one of the means to embed CSR into corporations. From this perspective, using contracts, contracting and contract management policies, processes, best practices, and tools to promote sustainability and to incentivize the green economy in organizations could be one of the means toward this end (Hirvonen-Ere 2019).

Summary

Embedded CSR means an approach that integrates CSR into an organization; and this is attained in a manner that involves its all core competences and affects all employees (Aguinis and Glavas 2013).

Embedded CSR brings several benefits to companies that apply it, such as competitive advantage. The competitive advantage is achieved via, inter alia, increased employee and stakeholder engagement and positive brand image (Greening and Turban 2000; Du et al. 2010; Carlini et al. 2019; Vilanova et al. 2009).

Embedded CSR, integrating CSR into the company, can be done via various management approaches. In addition to those, implementing ISO standards (Valmohammadi 2014), organization principles, and voice from the top from the management perspective (Swanson 1999, 2014) and utilization of contracts and contracting and contract management approach in an expanded manner (Hirvonen-Ere 2019) have been proposed.

Given the challenges of our time, in order to achieve the goals of corporate social responsibility in companies, the importance of CSR and embedded CSR in companies is likely to increase.

Integrated sustainability

Definition

The principles of embedded sustainability involve pursuing sustainable value, transforming business activities by offering smarter solutions in the life cycle and business value chain, as well as ensuring that sustainability is seen and taken by all as a responsibility (Annan-Diab and Molinari 2017;

Purkayastha and Rao 2017). Hence, embedded sustainability is often defined as incorporating environmental, health, and social value into the core business without sacrificing price or quality or charging a premium for being socially or environmentally conscious. Sustainability refers to achieving our goals without compromising the futures of coming generations (Elegbede et al. 2022, 2023). Along with natural resources, there are economic and social resources. Sustainability goes beyond environmental activism. Most conceptions of sustainability include considerations for social advancement and economic growth as well. It has a more decentralized grasp on productivity in the wider definition, a thorough understanding of environmental and social trends, as well as associated risks and possibilities, and may even promote innovation and experimentation that more generally improve it. Integrating all aspects of sustainability into a business element is known to improve embedded sustainability (Trollman and Colwill 2021). Businesses can incorporate sustainability through creative product and service design, investigation and appreciation, or reflection on experiences (Laszlo and Zhexembayeva 2011a). Embedded strategies address the growing demands on companies to define their mission and their strategy in line with the need to reorient globalization in favor of waste reduction, inequality reduction, a quick transition to a low-carbon economy, and biodiversity preservation (Elegbede and Guerrero 2016; Bertels and Dobson 2020). Clearly, embedded sustainability initiatives have a favorable effect on business productivity.

Concept of Embedded Sustainability

The practice of integrating environmental, health, and social value into a company's core operations without compromising quality or price, or, in other words, without charging a higher price for doing so, is known as embedded sustainability (Laszlo and Zhexembayeva 2011b). Environmental, health, and social principles are included in its primary business. The key to long-term success and growth is embedded sustainability, which

gives shareholders and the workforce new possibilities to discover purpose in organizational daily activities without sacrificing cost or quality. Every aspect of the business system must undergo a fundamental change in order to achieve embedded sustainability (IEDP 2011).

Sustainability involves adjustment, new knowledge, and cross-functional cooperation. Making this happen needs to fall under the purview of someone. The organization has included sustainability in its strategic plan and is making progress relative to its goals and objectives (Adams 2013). The organization's common objective vision, major strategy, and plans must include sustainability. Goals, material impacts, key performance indicators (KPIs), record keeping, target setting, and performance management are all necessary (Adams 2013).

Embedded sustainability as an innovative and fascinating concept pushes stakeholders, including human and non-human components of the institutions and entities to have a clear goal and scope that explores sustainable values toward engaging core sustainability in production and business (Fig. 1). Moreover, this concept enables the institutional framework to go beyond business as usual across the whole life cycle of products or services, particularly when designing strategies for having a thorough knowledge and management of the company to satisfy consumers and other stakeholders. To assist businesses in integrating their projects into their daily operations and decision-making, the embedding sustainability initiative creates a variety of resources that are useful in production (Bertels and Dobson 2020). Embedded sustainability is a response to a fundamentally altered market reality that unifies profit, not just a more environmentally friendly strategy. It necessitates dedication to upholding the moral standards and core principles of any organization's operations.

Pillars of Embedded Sustainability

Specifically, social responsibility, economic growth, and the environment are the three pillars that support sustainable development for a

Embedded**Sustainability,**

Fig. 1 Components of embedded sustainability. (Adapted from Laszlo and Zhexembayeva 2011b)

E

corporation. Prior to the importance of sustainability, three pillars were proposed. Explicitly incorporated into their formulation of organizations in a multidisciplinary and solutions-focused approach to sustainable development, the fundamentals of the sustainability framework are built on important and interconnected functions. Long-term commercial value can be generated when the purpose is integrated into all aspects of the company rather than being restricted to a sustainability team (Purvis et al. 2019). Because nearly all sustainable projects that are successful and scalable are driven by all three pillars simultaneously, the three-pillar framework is solutions-focused (Clune and Zehnder 2018).

The social pillar promotes implementing policies that advance societal well-being. Businesses should adopt flexible schedules and offer sufficient maternity and paternity incentive schemes in order to provide better engagement terms. Organizations should also offer enough opportunities for employee learning and growth to improve skills. Governments and other entities must be on the lookout for unfair practices in supply and production chains, such as child labor and worker exploitation. Organizations support the neighborhood. Through funding and grants, organizations can get involved in neighborhood projects including creating green spaces, schools, healthcare, and retirement homes and paternity incentive schemes in order to provide better engagement terms. Organizations should also offer

enough opportunities for employee learning and growth to improve skills. Governments and other entities must be on the lookout for unfair practices in supply and production chains, such as child labor and worker exploitation. Organizations support the neighborhood. Through funding and grants, organizations can get involved in neighborhood projects including creating green spaces, schools, healthcare, and retirement homes. Aside from providing grants and scholarships, organizations can also assist in promoting social harmony (Colson 2022). All these promote a societal approach to embedded sustainability.

For every firm, economic sustainability is frequently of the utmost importance. To achieve sustainability, a firm must be profitable. The economic pillar, however, opposes maximizing profits. Businesses must make profits while keeping in mind the other two pillars. Other actions that fall under the economic pillar include compliance, ecosystem governance, and job development. High employment rates help the economy and social welfare by creating jobs. According to the economic, social, and governance (ESG) criteria, this pillar is listed under corporate governance (Colson 2022).

The environmental pillar provides the legal framework, regulations, and other instruments of policy that address environmental issues. These challenges include the preservation of biodiversity, the conservation of natural resources,

animals, and threatened and endangered species, air and water pollution, treatment and disposal, environmental conservation, and solid waste management. This comprises financial incentives and market-based tools, including tariffs and tax relief, grants and subsidies, outreach programs, and education programs. The importance of the environment is further emphasized by SDGs 11, 13, 14, 15, and 16 (PFD 2022). At different levels, there exists a strong linkage between embedded environmental sustainability and the SDGs. Considering the global environmental sustainability goals and targets of the SDGs, it seeks to address critical environmental sustainability issues that affect the global environment and manage the escalating use of resources at various stages of development, which is known to cause environmental degradation. The environmental pillar advocates for improving air and water quality by reducing greenhouse gas emissions. It focuses on the welfare of the world (Colson 2022).

Embedded Sustainability Polarity

The concept of polarities is embedded in all transformation services as interdependent ideals that complement one another (Levknecht 2013). Most organizations, including those in the health sector, use it. Cells that are alive employ environmental polarity for an estimate. Local environments, such as districts, schools, and limited corporations, can use polarity management in resource exploitation. Creating sustainable value for polarities entails entities making decisions that take into account both the opportunities and dangers brought on by societal, environmental, and economic changes. To maximize the overall value collected, sustainable value creation demands systems thinking (Evans et al. 2017).

What Embedded Sustainability Means for Business Strategy

Sustainability is the incorporation of environmental, healthcare, and social benefit into the primary

strategy without compromising value or service and without charging additional fees for being socially or environmentally conscious. Managers underutilize the multiple levels of company value that embedding sustainability produces beyond just risk reduction or cost savings. In the world of business, sustainability refers to a company's plan to lessen the harm done to the environment as a result of its operations in a given market (IBM 2021). The goal of sustainability, therefore, entails unspoken decisions that are fundamental to company strategy, such as whether to explore progressive or revolutionary innovation and whether to eliminate negatives or create positive solutions. Productive, sustainable, and flexible business environments are integral to the foundations of economies and societies, like how wealth, job possibilities, and innovations produced by enterprises contribute significantly to life satisfaction (Woo 2020). Organizations must prioritize sustainability if they want to be relevant and competitive in today's marketplace. Stable business methods aim to employ resources that are renewable and non-polluting while also using less energy and materials. Sustainability will increase employee motivation to deliver better work, lower expenses, and have a 60% impact on operating profits. Implementing tactics that produce beneficial, long-lasting effects without jeopardizing the standard of living for future generations is the fundamental tenet of sustainability (Leeman 2022). Embedded sustainability helps organizations manage efficiency in the broadest sense more decentralizedly, has a deep understanding of social and environmental trends and possible consequences and prospects, and may even promote experimentation and innovation with better underside advantages (GP 2022). By incorporating sustainability into a company's fundamental business strategy, a corporation can increase value creation, manage risk, and solve the current environmental, social, and financial concerns facing the world (Mosher 2016). It allows a business to help with issues like the lack of water, climate change, inequality, and malnutrition. Utilizing alternative energy sources and carbon accounting, sustainability in business increases the effectiveness of energy management. Establishing

infrastructure that minimizes greenhouse gas emissions while protecting water resources and eliminating waste. Additionally, dynamic and effective supply chains are run to support a circular economy, stimulate reuse, eliminate waste, encourage sustainable consumption, and safeguard natural resources. Assessing risks and enhancing resilience while conforming to external norms and development objectives enables sustainable development (IBM 2021).

Implementation of Embedded Sustainability in the Business World

The implementation of a plan results in change that is intended to help the business or address a problem. Changes may be made to organizational development, budgets, budget allocations, processes, products, or services, among other things (Downes and Nicol 2020). Not underestimating the significance of implementation planning is vital for advancing a business. Everyone in a corporation is accountable for carrying out business implementation operations. All actions taken to fulfill one or more objectives in a company strategy are driven by implementation in the corporate sector. This applies to employees, managers, and firm executives. Each has significant responsibilities to ensure that their company successfully implements and executes strategic plans. However, the CEO ultimately bears responsibility for the execution plan's success. Furthermore, by incorporating embedded sustainability into business implementation, company employees at all levels can better understand their responsibilities and desired outcomes to work together toward a common goal, resulting in increased work performance and effective strategic goal implementation. Business implementation plans can ultimately help a company change for the better and flourish in a variety of important areas, such as corporate image, job satisfaction, organizational culture, income streams, and other critical areas. As a result, it promotes sensible corporate growth (Trollman and Colwill 2021). In the commercial world, one can accomplish goals such as obtaining clients, generating

income, or making a profit, among others, through implementation. Theoretically, there is no such thing as a "correct" or "incorrect" set of business objectives, but it is crucial to take the time to choose the most appropriate ones for your company and integrate them with sustainability goals (Trollman and Colwill 2021). The SMART (specific, measurable, attainable, relevant, and time-bound) framework is a trendy way to frame goals in embedded sustainability, and it can be helpful for creating objectives. It aids in the implementation of business setups throughout the world (Trollman and Colwill 2021). Embedding sustainability in business entails having a long-term approach to value creation by taking into account how the firm functions within ecological, social, and economic settings. Businesses who appreciate the significance of sustainability in a changing environment are seeking for methods to incorporate it into their business plans. Companies could explore investigating innovative methods to gather and understand data, being open in manufacturing and distribution processes, enhancing employee involvement, and implementing closed-loop production procedures throughout the supply chain to incorporate integrated sustainability in business (Trollman and Colwill 2021).

Achieving the Fundamental Goal

Ending poverty, preserving the environment, and ensuring everyone has access to peace and prosperity are all part of the sustainable development goals. These are the main tenets of the 2030 Agenda for Sustainable Development, which all UN member states accepted in 2015. (Vorisek and Yu 2020). Longer time horizons, a broader concept of value generation that encompasses system value, and alignment with the adaptability of the environmental, social, and economic context in which your organization operates are all factors that are taken into account by embedded strategies (Bertels and Dobson 2020). To eradicate poverty, safeguard the environment, and promote shared prosperity and peace is the sustainable development goal. These form the cornerstone of the 2030 Agenda for Sustainable Development, which was

endorsed by all UN member states in 2015 (Vorisek and Yu 2020). Longer time horizons and a larger knowledge of value generation, including systems value, are taken into account in embedded strategies in order to be regenerative and fit with the adaptability of the economic, social, and environmental setting in which your organization operates (Bertels and Dobson 2020). To boost business confidence, control threats, and fulfill a duty to support the global environmental agenda, the primary drivers are continual improvements in environmental, social, and governance (ESG) efficiency (Wijayasundara 2021). The country has a green power policy and may even benefit from the knowledge of high- and middle-income countries with similar environments. More generally, fulfilling the SDGs would require a flexible and interconnected global innovation system that actively links regions around the world, connects research actors with society, and promotes the co-production and exchange of locally relevant technology and knowledge (Stafford-Smith et al. 2017). ICT technology must therefore advance sustainably, and the creation of models must incorporate human understanding (Vinuesa et al. 2020). The use of sustainable business models can help organizations achieve their sustainability goals, generate and implement innovation for sustainability, integrate sustainability into their goals and operations, and gain a competitive edge (Bocken et al. 2014).

Embedded Future Sustainability

The future trends in defining sustainability embeddedness are social and ecological embeddedness. As an element of a sustainability transition, social embeddedness necessitates societal embedding. A shift in the relationships between economic players and the global ecosystems that benefit both is reflected in ecological embeddedness. Economy-wide integration is a side effect. However, in the existing capitalist system, economic factors limit the integration of sustainability (Trollman and Colwill 2021). Like quality, embedded sustainability is imperceptible. It is able to significantly motivate staff in addition

to providing consumers with products that are socially and environmentally conscientious. Most importantly, it makes it possible for wise businesses to increase revenue for both their stakeholders and stockholders in the future. Corporate sustainability with traits like embeddedness within the core business, providing sustainable value, and a transformative partnership is known as embedded sustainability. Excellent reading material with possible implications outside corporate audiences may be found in embedded sustainability. Making corporate sustainability a reality begins with incorporating sustainability into the strategic planning process, which is crucial but just the first step (Laszlo and Zhexembayeva 2011a). A company's brand and workplace culture can be impacted by sustainability, which can lead to new prospects and long-term growth. The planning, design, manufacturing, and maintenance processes must be fundamentally altered in order to achieve these advantages. For organizations to provide significant outcomes in the future, sustainability needs to be integrated throughout the entire structure. It is important to have visibility into performance indicators like resource utilization if sustainability is to be ingrained throughout a business. Companies have had access to this insight for longer thanks to advanced analytics (Leeman 2022). A number of frameworks (Trollman and Colwill 2021) address the business management imperative related to embedding sustainability. Embedded sustainability is utilized to create a novel paradigm to support innovative sustainable development that respects social and environmental embeddedness while acknowledging the impacts of the economic structure on business (Trollman and Colwill 2021). Through sustainability reports, important corporate governance resilience has been outlined as a decisive factor in a company's current engagement with the SDGs. In contrast, environmental, social, and governance (ESG) qualities like community relations are attributes that support embedded sustainability (Trollman and Colwill 2021). Thus, a plan for achieving a better, more viable future for everybody, with interwoven solutions. The objectives help formalize a common understanding of the need to eradicate poverty,

safeguard the environment, and guarantee that everyone lives in prosperity and harmony by the year 2030 (Bertels and Dobson 2020).

Ecological Entrepreneurship and Sustainable Food Systems

Beyond only advancing the economy, entrepreneurship has helped the modern world become more civilized. The concept of entrepreneurship is vast and complex. It involves investing significant time and effort, taking on the associated financial, psychological, and social risks, and reaping the benefits in the form of financial and personal happiness (Hisrich and Peters 1992). Initiating and carrying out projects that protect the environment, spread clean technologies, encourage recycling, and increase society's knowledge and awareness are all examples of ecological entrepreneurship. Its goal is to build a greener, more ecologically friendly economy (Mieszajkina 2016). It is commonly acknowledged that eco-entrepreneurship contributes significantly to reducing the adverse effects of businesses and individuals on the environment. It includes actions in the creation and implementation of clean production technologies (Huczek 2010), which use mineral resources sparingly, generate less pollution than they have in the past, and other technical measures taken to conserve resources and lessen or even eliminate any arduousness, pollution, and waste at the source, by putting non-technological innovations into effect, like new services and products, initiatives that have a minimal negative impact on the environment or allow for the most efficient use of resources to improve environmental education and develop ecological awareness programs. Depending on moral standards and the level of information regarding the ecological effects of acts made with respect to the environment, these complicated systems operate differently. The growth of eco-entrepreneurship is influenced by three primary categories of causes. The first group consists of tightening EU and international environmental standards, enhancing national and international legal regulations, streamlining

administrative processes, and providing financial incentives to promote environmental issues. The market for eco-friendly products and services is expanding quickly, which is the second category of variables. Consumer interest in purchasing organic goods is rising, which boosts manufacturers' output as the third set of elements (Mieszajkina 2016). The area of theoretical and applied research on sustainable development is growing. It is actively discussed in a variety of forums, national and international conferences, as well as scholarly and popular literature. A sustainable food system (SFS) is one that ensures everyone has access to food security and nutrient-dense food while maintaining the economic, social, and environmental foundations necessary to provide food security and nutrition for present and future generations. Sustainability is concerned with the economy, society, and environment. The sustainable development goals (SDGs) of the United Nations are centered on a sustainable food system. The SDGs, which were adopted in 2015, demand significant changes in agricultural production to eradicate hunger, ensure food security, and enhance nutrition by 2030. Many good things have come out of the advancements in food systems, particularly over the past three decades in developing nations. As the food industry has grown, these outcomes have included the increase of off-farm employment prospects as well as the expansion of food options beyond regional staples, satisfying customers' preferences for taste, form, and quality. The FAO's primary objectives, which include poverty alleviation, food security, and nourishment, are at the center of the food chain wheel framework (FAO 2014). These pertain to the three sustainability dimensions of social, environmental, and economic sustainability and are integrated into the system's overall performance. Entrepreneurship is crucial to the transformation of the global food supply chain toward environmental protection. The world's current food supply and its inherently unsustainable practices are inextricably linked to entrepreneurship. It is progressively promoting alternative activities to lessen the negative consequences of the global food system, such as fostering varied and local economies (Mars and Schau

2018). According to Barth et al. (2017) and Vlasov et al. (2018), embedding within the community is crucial for food production. Sharing information and networking is beneficial, and leveraging resources can be aided by trust and reputation in a socio-material setting (Bublitz et al. 2019; Batat 2021). Additionally, more sustainable ventures are more likely to be inspired when a place already has an entrepreneurial culture that supports sustainability (Enthoven and Brouwer 2020). Furthermore, because they rely on similar networks and frequently work together at multiple levels to establish sustainable food systems, stakeholders like the government and entrepreneurial actors who have an impact on entrepreneurship are difficult to separate in practice (Baldy and Kruse 2019; Desa and Jia 2020). The greater process of change can be captured by envisioning sustainable farming entrepreneurship as a continuous, periodic process of change rather than as a one-time picture of a company, product, or service. Entrepreneurship in the food industry that is sustainable is seen as a continuous cycle of development (van der Gaast et al. 2022). Innovation and entrepreneurship are essential for ensuring the longevity and resilience of our food production.

Sustainable Production

Sustainable production is the process of making or manufacturing goods using methods that are both economically sensible and minimize their adverse effects on the environment while preserving energy and other resources. Improved worker, community, and product safety is another benefit of sustainable production (EPA 2022). In the process manufacturing industry, eco-friendly manufacturing is getting more attention (Precog 2021). While maintaining societal safety and well-being all through the product life cycle, it seeks to create commodities with the least amount of natural resources and energy used and at the highest possible profit (Kumar and Mani 2021). Another name for this innovative new method of conducting business and adding value is

“sustainable manufacturing.” Numerous green products and practices that are popular and recognized in today’s society are the results of it. All types of businesses are now involved in programs and innovations that help create a healthier atmosphere, strengthen their competitive edge, lower risks, establish trust, encourage investment, draw clients, and make money (Wyckoff 2011). Using fewer resources, producing less waste, and emitting fewer emissions make it a more sustainable and effective system (Nasr 2022). The realization that present enterprises and lifestyles place too much emphasis on the economic side of things is what motivates sustainable manufacturing (Stark et al. 2016). Many organizations are interested in achieving sustainability because it can help them boost operational efficiency by cutting costs and waste, attracting new customers, gaining a competitive advantage, safeguarding, enhancing, and fostering the public’s trust, building a firm that will be successful in the long run, and adapting to regulatory opportunities and limits (EPA 2022). It is utilized in production, minimizes waste, and has a smaller negative influence on the environment. All layers of production, including the product, process, and system, should incorporate sustainable operations. The most crucial factor that must be taken into account by all industrial sectors is sustainable manufacturing. The life cycle assessment is the primary instrument for implementing sustainable manufacturing. It is a strategy to completely assess the environmental effects of various human activities, such as the creation of products and services by organizations (Posinasetti 2018). It can be used at the national or international level to identify environmental loads brought on by a society, a region, or an industrial sector. To achieve the objective of the earth’s self-recovery capabilities, three key concepts must be taken into account: decreasing the consumption of resources in the process, utilizing environmentally friendly materials, minimizing all forms of waste, and recycling and reusing as much material as is feasible (Posinasetti 2018). Avoiding ecological damage, eliminating pollution and emissions, limiting resource waste, consuming less energy, water, and other finite resources, and improving worker

and community safety are all aspects of sustainable manufacturing (Precog 2021).

Summary

Optimizing performance and minimizing resource footprints are two benefits of embedded sustainability for businesses. They create models that are driven by innovations that offer practical and long-lasting answers to problems with the environment and human health. For instance, embedded integrity promotes planetary well-being by guaranteeing that the earth's and ecosystems' integrity is preserved in a way that promotes organisms' well-being and the ability of numerous species and populations to continue in the future. The opportunity to discover the significance of life in the organization's system is expanded by embedded sustainability for stakeholders and employees. Therefore, the performance of businesses is positively impacted by embedded sustainability activities. Enhancing employee involvement, systems integration, and environmental protection are just a few of the economic and societal advantages that can result from incorporating sustainability into business operations and strategy.

Introduction

Emerging markets differ structurally from modern economies. As Khanna and Palepu (2010, p. 6) note: “emerging markets reflect those transactional arenas where buyers and sellers are not easily or efficiently able to come together.” Differences between emerging and more developed markets can be found, for example, from markets’ capacity to tolerate external shocks and to provide stable enough operational environment for market actors to operate. Differences can also be found from the capacity of public institutions to support entrepreneurial activities, to provide financial opportunities for market actors, and to generate long-term predictability to the markets (Khanna and Palepu 1997). Due to these differences, modern markets have traditionally attracted more investments than emerging markets. This development, however, is changing, and during the past few decades, emerging markets have become significantly stronger players in the global economy (Kose and Prasad 2010).

A specific definition for the concept of the emerging markets is challenging to construct, and its development leads to diverse directions among scholars and practitioners. Some authors highlight the diverse opportunities and the overall socioeconomic potential of emerging markets (Agarwal et al. 2018; Ernst et al. 2014), whereas others adopt a more critical perspective arguing that the concept of emerging market carries the burden of colonialism and aims to extend Western version of capitalism into sociocultural contexts where it does not naturally belong (Akbar 2006). Regardless of the perspective, it must be emphasized that emerging markets are heterogeneous group of economies and societies that are in different stages on their way from closed and controlled economy to more open markets. It is also important to understand that emerging market is a strategically oriented concept that can be used to drive diverse agenda in different situations.

Key Sustainability-Related Issues in Emerging Markets

Sustainability change materializes in different ways in different parts of the world (Sachs 2015). While developed economies, especially in Europe and North America, are increasingly facing the negative side effects of their overconsumption, large emerging areas are continuing to increase consuming opportunities for their growing population to reach the northern living standard. As emerging market countries are, by definition, in the path of becoming more affluent, people in these countries are expected to have more purchasing power in the future. At the same time, in many emerging market countries, the economic growth is fast. Regardless of the relatively low basic level, economically more affluent middle class is enlarging and having more political power than before. Due to large number of people having more opportunities to consume, the major sustainability challenge is to decrease the negative environmental impacts of consumption.

It is important to consider the diversity of emerging market countries in sustainability management. The ecological carrying capacity of the globe cannot cope with increased consumption, especially if consumption stays material and energy intense as it has been since Industrial Revolution. To reduce the negative implications of increased consumption opportunities, businesses in emerging markets will need to shift toward utilization of sustainable and circular business models, which is very challenging task if the operational environment does not support such development (Levänen et al. 2018). This shift must be facilitated in different ways in different emerging market countries. Countries where institutions of environmental management are weak or not existing will need external support to build up well-functioning operational environment that supports sustainable development. Countries where institutions start to be in place will need support for companies to develop their business models toward increased sustainability.

Global sustainability challenges, such as climate change, biodiversity loss, and unsustainable use of natural resources, are serious threats at emerging markets, but challenges also vary between the countries. Many emerging market countries especially in the Global South are struggling with uncontrolled urbanization and large structural poverty, both of which bring in other problems including lack of basic services such as proper health care, energy, food, and safe drinking water. If urbanization happens rapidly and without planning, it may increase social and geographical segregation and accelerate sustainability challenges. At the same time, other emerging market countries, such as Brazil and Russia, suffer from other types of environmental and social hazards including forest fires and violations of human rights of indigenous peoples. Management of these diverse challenges requires different approaches and strategies in different contexts.

The sustainable systemic transition (see ► [“Systemic Transition”](#) in the chapter by Koistinen et al., this volume) is urgently required in solving the sustainability challenges and supporting the equal development in the emerging markets.

Summary

To avoid speaking about the “third world countries,” which contains a negative connotation, World Bank’s economist Antoine van Agtmael introduced term “emerging market” in 1981. Generally, emerging market refers to low-income level economies with limited functions. At the same time, these countries are in the process of development toward more affluent and more efficiently functioning modern economies. Majority of the emerging markets locate in Asia, Eastern Europe, Africa, and South America, the four largest, so-called BRIC countries, being Brazil, Russia, India, and China. Recently, more and more previously stagnant and poor economies join in the group of emerging markets. Currently, some of these countries

are among the fastest growing markets in the world.

Employee Downsizing

Lars Schweizer and Eva Maria Katharina Koscher

Description

With regard to the business context, downsizing refers to the process of decreasing the number of employees on the operating payroll. Usually, downsizing is a strategic move implemented with the intention to improve firm performance (Cascio et al. 1996). Some researchers distinguish between downsizing and layoffs, with downsizing defined as a permanent reduction of employees and layoffs defined as a downscaling which is only temporary and where employees may later be rehired. Most often, however, the terms downsizing and layoffs are used interchangeably.

Companies use a number of methods in downsizing, including setting financial incentives for employees to take early retirement or providing opportunities for a transfer to subsidiary companies. Still, the practice used predominantly is to simply terminate the employment of a certain number of employees. Downsizing is sometimes necessary, but it should never be taken lightly since it can have a severely negative effect on people and companies (Datta et al. 2010).

Introduction

Downsizing, defined as the “*intentional, permanent, and systematic reduction of an organization’s workforce*” (Nixon et al. 2004, p. 1122), is a socially questionable strategic management practice that was once confined primarily to the

United States, but has become more and more omnipresent in recent years (Datta and Basuil 2015; Datta et al. 2010; Nègre et al. 2017). Especially during the recent economic crisis, news of corporate downsizing has been prominent in the media around the globe. It is, however, not a new phenomenon. Companies reduced their workforces also in the late 1980s and early 1990s using various methods such as layoffs, plant closures, and early retirement programs (Davidson et al. 1996). In addition, firm executives often claim that downsizing is an essential strategy to deal with the hostile and dynamic environment companies are embedded in, and which may even be crucial to a company's survival in times of economic turbulence or during recessions (Appelbaum et al. 1999; Budros 2002). Previous research, however, has shown that employee downsizings usually mean substantial losses for employees and the local community and are normally perceived as a breach of the social contract between a company and society (Nègre et al. 2017).

Effects of Downsizing

Presumably, firms reduce their workforce to improve their performance (Cascio et al. 1996), and newspaper stories often report that downsizing announcements lead to a stock price increase for companies making such announcements as the market views them as a positive sign regarding a firms' expected future profitability (Abraham 2004; McKinley et al. 1995; Neus and Walter 2009). Nevertheless, the political reaction against downsizing and the public criticism of this practice is high. And another point speaks against downsizing decisions: research found that the economic effects of downsizings on companies are not unambiguous. Downsizings often fail to bring the sought financial effects since the direct and indirect costs coming with them (e.g., reorganization costs, costs for social plans, severance payments, a negative impact on company reputation, declines in employee motivation or devotion) regularly prevail over the cost savings (Datta et al. 2010;

Cascio 2009; Flanagan and O'Shaughnessy 2005; McKinley et al. 2000).

Stock Market Effect of Downsizing

A number of empirical studies have closely examined the stock market's reaction to layoff announcements, with studies presenting mixed results (please see Datta et al. (2010) for an overview). While negative effects of downsizing have been found in most of these studies (e.g., Hillier et al. 2007; Lee 1997; Nixon et al. 2004; Worrell et al. 1991; among others), some studies found positive effects (e.g., Brookman et al. 2007; Chadwick et al. 2004; Chalos and Chen 2002; Collett 2004; Wayhan and Werner 2000), or no effects at all (e.g., Cascio et al. 1996). As a result, researchers have concluded that downsizing might result in differing effects in different situations (De Meuse and Dai 2013) and that especially the reason for a layoff and the financial condition of the company have moderating effects (Abraham 2004, 2006; Filbeck and Webb 2001).

Most researchers analyzing the relationship between downsizing and firm performance have explicitly or implicitly adopted an economic perspective and assume that companies implement downsizings to reduce costs, increase efficiency, and ultimately improve a company's financial performance (McKinley et al. 2000; De Meuse and Dai 2013). While early research investing this theory was mainly based on management and employee perceptions of the downsizing results, recent studies have primarily employed the event study methodology to investigate the financial consequences of a downsizing decision (Datta et al. 2010; Neus and Walter 2009). Worrell et al. (1991) can be treated as pioneers here as they were the first to study the link between downsizing announcements and stock prices using this methodology. In an event study, the realized returns to a company around a specific event (e.g., a downsizing announcement) are compared to a prediction of what those returns would have been without the event's occurrence. The difference between the realized and the predicted returns is then credited to the event under examination (Abraham 2004). Introduced by Dolley (1933) and mainly influenced by Fama et al.

(1969), the event study methodology can be seen as the standard method of measuring the influence of specific events or announcements on the stock price (Binder 1998).

Explanations for a Negative Effect of Downsizing

Explanations for the negative effect of downsizing on a company's financial performance are given by the *Psychological Contract Theory* (Morrison and Robinson 1997) and by the *Declining Investment Opportunities Hypothesis* (Elayan et al. 1998). The psychological contract comprises a set of reciprocal obligations that arise during an employee's tenure with a company (Rousseau 1989). De Meuse et al. (2004) outline that employees are expected to work hard and support the company's goals, while the company is seen as responsible for providing a stable environment, offering competitive wages, and providing prospects for individual progress and promotion. Therefore, employees will perceive layoffs as a breach of contract. This can, in turn, have an adverse effect on the behavior of the remaining employees and subsequently lead to lower firm performance (Morrison and Robinson 1997). Accordingly, investors will interpret layoff announcements as a sign of lower future performance, and the share price will drop. Elayan et al. (1998) further argued that layoff announcements might reveal that the company has fewer investment or growth opportunities as previously assumed.

The Effects of Downsizing on Surviving Employees

One of the most common reasons why downsizing companies perform below par is that they frequently only seem to think about the employees who are to be released but are not anticipating the decreased commitment and lower productivity the remaining employees exhibit after the downsizing (Isabella 1989). Downsizing normally causes resentment and resistance in surviving employees. Research has shown that employees often report decreased motivation and are less productive after layoffs, a phenomenon named the “*survivor syndrome*” (van Dick et al. 2016). So, unfortunately,

at a time where a company needs its employees at their best, they occur to be at their worst (Buchholz 1993).

Previous studies identified key concerns with regard to downsizing and surviving employees. It has been found that remaining employees are often misinformed or not informed at all about many important issues (e.g., their role in the newly structured company, the projected performance standards or extra work demands, whether or not certain key people in existing networks are leaving, or just, in general, the value of their expertise and know-how to the restructured company). Such information problems are further amplified by financial and job insecurities (Isabella 1989).

Summary

Downsizing refers to the process of decreasing the number of employees in a company and is usually a strategic decision to improve firm performance (Cascio et al. 1996). Research has shown that downsizings regularly fail to bring the anticipated financial results due to the fact that the direct and indirect costs of layoffs often outweigh the cost savings (Datta et al. 2010). Therefore, companies contemplating downsizing decisions should take into consideration all future consequences of layoffs before deciding on such a decision.

Employee Engagement

María D. Odriozola, Ignacio Llorente and
Elisa Baraibar-Diez
Business Administration, University of Cantabria,
Santander, Cantabria, Spain

Synonyms

Commitment; Empowerment; Involvement; Job engagement; Work engagement

Definition/Description

Employee engagement (EE) is one of the objectives of human resources management, since a greater EE with the company increase work performance through greater efforts, productivity, positivity, and efficiency. Employee engagement is determined by organizational, emotional, behavioral, and cognitive variables.

Introduction

The concept employee engagement (EE hereafter) is contextualized in the human resources management (HRM) of companies (Guest, 2014). There are two opposing models well distinguished in the management of human resources from a normative perspective: traditional management and management by commitment (Tena et al., 2002). Traditional HRM, represented by Taylorism, advocates the maintenance of command hierarchies and the supervision of workers. In contrast, employee engagement is the key element of a management model based on increasing job engagement, where employees participate in

company decisions, and they are autonomous and assume greater responsibility.

The interest to increase the employees' engagement is greater currently due to the expected outputs. Previous studies in this field argue that greater engagement provides greater motivation to the employee, which makes them more creative and more innovative in their work and have more proactive behavior towards learning (Koner mann, 2012; Bakker & Xanthopoulou, 2013; Bakker et al., 2014). In addition, employees who are more committed to their company have less stress, are more proactive, and maintain better health (Bakker et al., 2014). At the organizational level, when employees have a higher level of employee engagement, they are capable of transmitting positive emotions to their collaborators in the company, which not only means an increase in individual performance but also it is positive for the whole team performance (Xanthopoulou et al., 2009). Last, but not least relevant, employee engagement is an important predictor of customer satisfaction, because the quality of the service increases and in the long term, customer loyalty also is increased (Harter et al., 2002; Salanova et al., 2005; Bakker et al., 2014).

Employee engagement cannot be considered an isolated term in HRM, because the level of EE will be affected by organizational aspects, behavioral aspects, and collective and individual perceptions of the employees. Figure 1 shows the *Strategic Engagement Model* proposed by Albrecht et al. (2015). According to this model, HR practices in the areas of recruitment and selection, socialization, performance management, training, and promotion, among others, generate a certain organizational climate that consequently generates different job demands (JDs hereafter). JDs are those requirements that need any kind of extra effort (physical, emotional, or cognitive) (Demerouti et al., 2001). JDs, as stress or work pressure, maintained over time produce fatigue and discomfort to employees; as a result, JDs are often considered predictors of burnout.

On the other hand, employees not only respond to JDs but also have job resources (JRs). Job resources "are those aspects of the job that help to achieve work goals, reduce job demands, or

Employee Engagement, Fig. 1 Strategic Engagement Model. (Source: Albrecht et al. (2015))

stimulate personal growth” (Bakker et al., 2014). That is why job demands-resources theory (JD-R model) (Bakker & Demerouti, 2014) has gained prominence to explain employee engagement, in addition to the fact that the model proposed by this theory is applicable to all work contexts. However, this is not the only theory that supports the study of employee engagement. As we mentioned before, human resources practices are essential to increase commitment, so there is a theory to explain EE in relation to HRM. Human Resource Development (HRD) theory focuses on managing and transforming the organization to reduce the gap between current performance and desired performance level (Kwon & Park, 2019).

Taking all the above into account, and returning to the *Strategic Engagement Model* (Fig. 1), EE depends on the way employees adapt their work to their personal characteristics (job crafting) and the employees’ perceptions and feelings (e.g., their motivation or feeling of labor safety) in relation to the job resources and job demands. All these previous variables form a particular atmosphere that will give rise to different degrees of engagement, and from this, companies obtain different outputs (Albrecht et al., 2015).

However, this combination of variables to obtain the EE cannot forget to include individual factors, such as the individual’s personality

(called *trait personal resources* in Fig. 1). Academic literature identifies several aspects of the personality that have a positive relationship with engagement, emotional stability, extraversion, and conscientiousness (Mäkikangas et al., 2013), as well as the personal resources affected by personality, such as self-efficacy, optimism, self-esteem, and work commitment (Xanthopoulou et al., 2009). The fact that the concept EE has positive impacts on the outputs of the company means that many authors have tried to define the concept in relation to a diversity of terms. However, the lack of unanimity to define and measure the concept does not make this concept a meaningless concept, but rather it needs to be understood within a context of related variables.

Definition of Employee Engagement

The definition of the term employee engagement appears in the literature with different nuances depending on whether the term is in relation to (a) the attitudinal and behavioral part of the employee; (b) the motivation, satisfaction, or work environment; or (c) the outputs obtained according to the level of engagement. However, despite the different definitions found, there are multiple similarities between them (Table 1).

Employee Engagement, Table 1 Definitions of employee engagement

Authors and year	Definition of employee engagement
Kahn (1990)	“Harnessing of organization members’ selves to their work roles: in engagement, people employ and express themselves physically, cognitively and emotionally during role performances” (p. 694)
Maslach and Leiter (1997)	“Engagement is characterized by energy, involvement, and efficacy, the direct opposites of the three-burnout dimensions. These authors argue that, in the case of burnout, energy turns into exhaustion, involvement into cynicism, and efficacy into ineffectiveness”
Schaufeli et al. (2002)	EE is “a positive, fulfilling, work-related state of mind that is characterized by vigor, dedication, and absorption” (Schaufeli et al., 2002, p. 74)
Wellins and Concelman (2005)	Engagement is “an amalgamation of commitment, loyalty, productivity and ownership” Engagement is “the illusive force that motivates employees to higher (or lower) levels of performance”
Macey and Schneider (2008)	Employee engagement is a desirable condition, has an organizational purpose, and connotes involvement, commitment, passion, enthusiasm, focused effort, and energy, so it has both attitudinal and behavioral components
Christian et al. (2011)	EE is “relatively enduring state of mind referring to the simultaneous investment of personal energies in the experience of work” (p. 95).
Shuck et al. (2017)	EE is “an active, work-related positive psychological state operationalized by the intensity and direction of cognitive, emotional, and behavioral energy” (p. 2)

Source: Authors

Most definitions mention that EE would derive in applying greater efforts in daily work, alluding to the behavioral part of the employee. Many contributions include in the definition of

engagement an emotional or personal component of the employee, noticing that the personality and the state of mind of the worker will also play a role in determining engagement. Finally, many definitions also focus on the development of engagement with an organizational purpose of increasing its performance and obtaining a more effective workforce.

HR Practices to Create Engagement

The creation of EE is not easy. It does not offer a single pattern of behavior through which, following a series of HR practices, companies can obtain the same result. Knowing concrete practices to increase EE would be interesting for practitioners in the HRM. In previous studies, we found a high level of agreement in the categories that should be considered to describe EE, although there are doubts when it comes to specific human resources practices. For example, it is not clear whether providing training to improve employee skills increases commitment (Truss et al., 1997). The same doubts occur with the performance-based pay system (Becker & Gerhart, 1996) or greater communication and autonomy (Osterman, 2000). Furthermore, specific HR practices often do not have the expected impact on employee engagement, and some Industrial Psychology studies defend the creation of engagement through the norm of reciprocity (Gouldner, 1960). According to the reciprocity rule, EE is generated when employees perceive that the company responds to their needs and concerns and that their work is being valued. If employees perceive that the company cares about them, they will respond to these stimuli with a greater degree of commitment.

However, communication between employees and company management will be essential to increase the desired perceptions in the employee (Tena et al., 2002). Adequate two-way communication between the employee and the manager (or company management body) will increase employee confidence. In this sense, the study by Macey and Schneider (2008) conceptualizes EE

Employee Engagement, Fig. 2 Framework for understanding the elements of employee engagement. (Source: Macey and Schneider (2008), p.6)

in three differentiated phases (see Fig. 2). Firstly, the EE will be determined by aspects of the employee's personality (such as proactivity, positivity, conscientiousness), to which conditioning aspects of the workplace will be added (such as nature of work, challenge, variety, and autonomy) that will moderate the result of the second phase "state engagement." To move to the third phase, "behavioral engagement" will be directly affected by the leadership style exercised in the company and indirectly by the trust generated between the parties. For this reason, practices related to communication and positive leadership will help build trust; and it is expected to increase the EE.

Main Measures of Engagement

The measurement of EE is not clear in the academic literature; in fact, in most studies, its measurement can be given by one or more psychological and behavioral components. Some of the most representative measurements of "employee engagement" would be classified in the following categories:

1. *Job satisfaction.* Employees assess their satisfaction with the company in different aspects. EE can be measured as direct evaluations of satisfaction with the company, manager, work group, job, and characteristics of the work environment (Burke, 2005). A measurement of engagement entirely based on satisfaction would present weaknesses however, since it is theoretically expected that with higher EE, higher levels of performance are found. Despite being correlated with engagement, satisfaction is sufficiently characterized by a sense of well-being and pleasantness connoting at best moderate levels of activation or energy (Macey & Schneider, 2008), but there is no any additional effort in the development of their work.
2. *Enthusiasm, dedication, or passion.* Enthusiasm is considered a measurement of commitment by some authors (Harter et al., 2003). Unlike satisfaction, which denotes a positive feeling toward the organization, when we refer to the enthusiasm of the worker, it would be referring to proactive attitudes, where the employee shows greater predisposition or

dedicates greater efforts at their discretion, beyond what is required to contribute to the company. According to those who advocate this type of commitment measurement, when a worker feels engagement, he would show high levels of energy, resilience, and perseverance in the face of difficulties (Bakker et al., 2014).

3. *Job commitment*: According to Macey and Schneider (2008), job commitment “is conceptualized as positive attachment to the larger organizational entity and measured as a willingness to exert energy in support of the organization, to feel pride as an organizational member, and to have personal identification with the organization.” Unlike the previous measurements, the commitment gives greater attention to the pride of belonging to the organization or the identification with its values.

These categories are not exclusive, and in some studies, they form combined measurements. There are also other proxy variables, perhaps less used to measure EE, such as *involvement*, where the degree of participation or contribution felt by the worker in their work would be given greater prominence, or *empowerment*, where aspects related to self-efficacy in the position, autonomy, or responsibility would come into play. Thus, EE is a multidimensional construct, whose measurement is complex and interrelates psychological, organizational, and behavioral aspects. Most of these measurements of engagement through multidimensional indicators are carried out through employee surveys, where they respond according to the degree of agreement or disagreement they have with representative phrases of the categories mentioned above. One of the most used scales that includes aspects classified into three categories (vigor, dedication, and absorption) is the questionnaire called *Utrecht Work Engagement Scale (UWES)* (Mills et al., 2012; Kwon & Park, 2019). There are also highly recognized questionnaires such as the *Employee Engagement Scale* which consists of three sub-constructs (cognitive, emotional, and behavioral) (Shuck et al. (2017), *Work Cognition Inventory (WCI)* (Nimon et al.,

2011), and *Intellectual, Social, Affective (ISA)* (Soane et al., 2012).

Employee Engagement in Academic Literature

Employee engagement has been studied in the academic literature with different purposes: on the one hand, the identification of HRM practices based on soft skills that allow increasing employee participation in the company and on the other hand, the focus on increasing employee commitment and as a consequence business performance.

Figure 3 shows the evolution of the papers available in the Scopus Database with the following search criteria in the title, abstract, and keywords parameters: “employee engagement” or “job engagement” or “work engagement,” limiting the results to articles.

The studies related to employee engagement have a notable growth from 2005 onward, despite the fact that the first definition of the concept was published in 1990. In Fig. 4, we can see the 15 authors who have published the greatest number of publications on employee engagement. In this sense, the figure of Bakker, Shaufell, and Demerouti is noteworthy. These 3 authors have more than 50 papers in this area of research.

The journals that have published a greater number of papers on “employee engagement” are the *International Journal of Environmental Research and Public Health* and *Frontiers in Psychology*, both hosting more than 100 papers each. Table 2 shows the ranking of the five journals with the highest number of publications on the concept discussed. Finally, Fig. 5 shows how employee engagement has been treated in different subject areas, although research in the Business, Management, and Accounting area is predominant, since it has received 27.3% of all publications to date (Data consulted in July, 2021). The areas of Psychology, Social Sciences, and Medicine also stand out behind the aforementioned area, from highest to lowest importance following the order in which they have been mentioned.

Key Issues and Future Directions

One of the main conclusions derived from the analysis of the concept “employee engagement” is that it is a construct affected by behavioral, emotional, organizational, and cognitive variables. This aspect makes it necessary to create complex models to

explain employee engagement, and that the results differ individually among the employees of an organization, since the personality and emotions of the individual affect their commitment to the organization. Regarding the definition of the term, there are various definitions, although most authors have many aspects in common. They highlight that the

EE shows a greater involvement of the employee that is made visible in a behavioral way with a greater effort and dedication in the work development, which will subsequently lead to higher performance. In its measurement, it is where the greatest divergences can be found, where the main proxies used are satisfaction, dedication, and commitment.

The concept of “employee engagement” is relatively new in the literature, since most studies are quite recent. In this sense, and

considering that the actions of HRM, the business management style, and the resources provided affect employee commitment, it will be necessary to analyze this concept in different sectors and employment contracts. Currently, many workers have jobs with less physical ties to their company and to the rest of the collaborators. This is, for example, the case of workers hired in a teleworking modality. It would be interesting to investigate whether there are significant differences in the level of engagement depending on the modality in which the work is carried out.

Summary

Increasing employee engagement is an aspect of growing interest in the field of management, more specifically in human resource management. However, there are certain aspects about this concept that must be considered: (1) It is not a simple measurement concept. (2) It is a concept that can be affected by organizational, emotional, behavioral, and cognitive variables, thus its explanation

Employee Engagement, Fig. 5 Evolution of articles with the concept “employee engagement”. (Source: Scopus Database on July, 2021)

requires complex models that show the relationship between a set of variables. This is confirmed by the “strategic engagement model.” It shows how engagement is affected by demands on employees, the resources offered to them, and individual variables of the worker. Regarding the definition of the term, this contribution provides current definitions that allude to attitudinal, behavioral, and motivational aspects of the employee, as well as the outputs derived from the employee engagement. Finally, two questions are answered: (1) How is employee engagement increased? and (2) How is engagement measured? Finally, a review of the academic literature is carried out, identifying the main authors and publications that have worked on the construction of the term, as well as future proposals to increase knowledge about it.

Employee Participation/Ownership

Definition

Employee participation/ownership identifies the workers' shareholding in their employing company (Kaarsemaker et al. 2010; Kruse 2002; Sausser 2009). Thereby, the employee participation/ownership provides workers not only with their traditional prerogatives but also with cash-flow, dividend (Duncan 2001; Sengupta et al. 2007; Wagner et al. 2003) and control rights (e.g. decision-making involvement in company management and opportunity to achieve

information on firm operations/activities (Black et al. 2007; Kaarsemaker et al. 2010; Rousseau and Shperling 2003).

It is worth noting that the use of such governance tool dates back to the mid-1950s when the employee ownership has been adopted for the first time by a North American attorney and investment banker (i.e., Louis Kelso) (Blair 1995; Freeman 2007). Since then, the debate around the topic has strongly involved both academics and policy makers (Kalmi et al. 2005; Pierce et al. 1991; Poutsma et al. 2006). However, while at the beginning their discussion has been mainly focused on the use of such tool by the workers' cooperatives, from the 1980s onward it has shifted toward the adoption of employee stock ownership by corporations (Logue and Yates 1999; Park et al. 2004; Pierce et al. 1991).

Moving from these premises, the chapter provides an overview on the taxonomy and the aim of employee participation/ownership and illustrates the scholarly debate on the topic by focusing the attention on the issues related to its adoption.

Classification, Aim, and Scholarly Debate on Employee Participation/Ownership

Academics identify different specifications of employee participation/ownership and provide the categorization of the phenomenon under scrutiny on the basis of a number of factors. In particular, the most common classifications used for this governance tool are based on the proportion of workers with ownership stakes, the percentage of shares held by employees, the type of ownership (i.e., direct or indirect), and the rights provided to the beneficiaries by the ownership stakes (Kruse 2002; Sesil et al. 2003).

Overall, the employee ownership takes a variety of forms as workers can participate in the ownership of the related employer by acquiring, individually or collectively, a proportion of the company shares. In addition, the employee participation/ownership can be designed by limiting the beneficiaries to few workers or broadening the company

ownership to all the firm's employees. At the same time, the above-mentioned plan can hamper or expand the extent of the worker rights in terms of participation to the company profit, risks, and information sharing (Ben-Ner and Jones 1995).

With regard to the adoption of the tool under scrutiny, it is worth noting that the workers' participation/ownership can originate from an employee buy-out or the decision of existing owners to pass on the business to workers (Degeorge et al. 2004). However, in some cases, the employee participation/ownership stems from the use of incentive remuneration plans as it is one of the most common components of the grants rewarded to the related beneficiaries (Blasi et al. 2003; Core and Guay 2001; Lawrence 1987).

Despite the differences among the specific types of employee participation/ownership, the common feature of all the employee-owned firms is the ability to build a strong sense of involvement among the beneficiaries by fostering their active participation in the governance and managerial activities of the company (Black et al. 2007; Kaarsemaker et al. 2010).

From a theoretical standpoint, the rationale behind the adoption of the employee participation/ownership relies upon the tenet that the involvement of workers in the company ownership is able to align their conflicting interests to those related to firm owners as described by the agency theory (Berle and Means 1932; Jensen and Meckling 1976). Indeed, following this approach, scholars highlight that the governance tool under scrutiny limits the workers' opportunism and hampers their extraction of private benefits to the detriment of shareholders (Shleifer and Vishny 1997).

According to the agency proponents, this effect is mainly due to the ability of employee participation/ownership to modify the perspective of workers so as to identify themselves with the firm shareholders (Duncan 2001; Jensen and Meckling 1976). The underlying premise of the above-mentioned alignment relies on the reciprocal dependence between the beneficiary of the company outcomes and the firm performance (Pendleton 2006; Sausser 2009; Sengupta et al.

2007). Thereby, the employee participation/ownership links the workers' goals to the company results to provide them incentives to the firm value maximization by building the related motivation, commitment, and cooperation (Blasi et al. 2003; Duncan 2001; Wagner et al. 2003).

Based on these premises, both scholars and practitioners emphasize that the ownership involvement of workers offers a number of benefits to the company. First of all, it hampers their myopia and motivates employees to take value-maximizing decisions by discouraging the short-term opportunistic behavior (Fudenberg et al. 1990). Second, it prompts the beneficiaries of employee ownership to improve the quality of their performance while enhancing the related cohesion and productivity (McCarthy and Palcic 2012). Third, it supports the equitable distribution of the firm wealth among all the parties involved in the value creation (Harrison et al. 2018). Moreover, from a different standpoint, it is considered as a solution able to foster the inclusive participation of stakeholders to the company activities by increasing their involvement in the firm decision-making process (Bernstein 1976; Freeman 2007; Gates 1999; Grunberg et al. 1996).

Opposite conclusions are drawn by the opponents of employee ownership as they highlight that the involvement of workers is not only able to improve the conflicts with managers but it also limits the participation of workers and enhances the related risk exposure (Harrison et al. 2018; Storey et al. 2014).

Despite this criticism, from the 1970s onward (Freeman 2007), the employee participation/ownership has been widely spread used by Anglo-American and European companies alike (European Federation of Employee Ownership 2008; Mygind 2012; Park et al. 2004; Poulain-Rehm and Lepers 2013; Reeves Knyght et al. 2010). Illustrative of this phenomenon is the circumstance that the first studies on the employee share ownership date back to the late 1970s when academics have started to investigate the majority employee ownership (Long 1978).

In particular, literature in this tradition has explored the effects of the governance tool under scrutiny on the employee behavior (Rhodes and Steers 1981) and the workers' participation in the decision-making process of the related companies (Dewe et al. 1988; Hammer et al. 1982; Long 1981). In addition, earlier studies on the topic have examined the implications of employee ownership for trade unions (Hammer et al. 1982; Stern et al. 1983). Aside this line of inquiry, the researchers' attention has been also devoted to assess their perception by the company workers and the related outcomes for the adopters (Caramelli and Briole 2007; Freeman 2007; Heras-Saizarbitoria 2014; Klein and Hall 1988; Pendleton et al. 1998; Poutsma et al. 2006; Reeves Knyght et al. 2010; Wichman 1994).

At the same time, a second strand of research has explored the performance implications of the employee participation/ownership offering mixed interpretations of the phenomenon under investigation (Conte and Svenjar 1990; Frye 2004; Long 1980). In particular, some studies in this tradition have documented that the employee participation/ownership negatively affects the firm performance (Guedri and Hollandts 2008) as this governance tool concentrates the control over the company's activity without providing employees with an effective motivation to improve their productivity (Park and Song 1995).

However, opposite conclusions are drawn by a competitive strand of studies finding that the presence of employee share ownership enhances both the company profitability and the shareholder returns (Kruse and Blasi 1997; Kumbhakar and Dunbar 1993; Mitchell et al. 1990; Park and Song 1995; Sengupta et al. 2007).

Aside this line of inquiry, another group of research has explored the effects of the employee participation/ownership for the company survival. In particular, studies in this tradition have reported that the employee-owned firms survive longer than companies that are not characterized by the workers' share ownership (Blair et al. 2000; Blasi et al. 2013; Park et al. 2004).

Despite the benefits of using this governance tool, it is worth noting that there are remarkable differences among countries with respect to its presence (Kaarsemaker et al. 2010). Following a law and finance approach, this circumstance can be explained in the light of the legal protection of investors provided by the regulation in force in each setting (La Porta et al. 1998, 1999). In this regard, as suggested by the literature, the presence of limited investor protection can provide the beneficiaries of employee ownership with incentives for the entrenchment of shareholders and may also foster the extraction of private benefits to the detriment of the company (Bebchuk and Fried 2006; Dyl 1988; Jensen et al. 2004).

On the basis of these premises, proper policy-making interventions are called to strengthen the pivotal role played by the employee participation/ownership and remove the distortions of the limited investor protection in the countries where this tool can support the company growth and the value creation.

Summary

The manuscript illustrates the types of employee participation/ownership and discusses the rationale of the related adoption by providing an overview on the academic debate on the topic.

Definition

As a relatively new concept, employee sustainability behaviors (ESB) refers to the workplace behaviors directed toward improving environmental, social, and economic sustainability in organizations that are performed by employees at any organizational level (Ciocirlan 2017). To identify the nature of ESB, a distinction is typically made between discretionary (voluntary, extra-role) sustainability efforts and those that are required (mandatory, in-role) based on congruence to the organization's internal standards and procedures (Norton et al. 2015; Boiral and Paillé 2012). The difference is essential as most discretionary sustainability behaviors are not recognized by formal organizational processes. While required ESB is performed within the typical job duties, voluntary ESB entails personal initiatives that go beyond task requirements and organizational expectations (Norton et al. 2015). While all behavioral categorizations of ESB (e.g., in-role vs. extra-role, low-intensity vs. high-intensity) rely on some common ideas and principles of ► [corporate sustainability](#), each has also its own unique set of determinants, conditions, processes, and outcomes.

Micro Foundations of CSR

The micro foundations of ► [corporate social responsibility](#) (CSR) – the roots of CSR that are based on individual actions and relationships – have a prominent role in explaining sustainable behavior in organizations. Even though corporate responsibility issues can be examined at different levels, individual-level analysis has been very limited compared to studies at institutional or organizational level (Aguinis and Glavas 2012). Despite this scarcity, there have been increasing attempts in identifying the fundamental processes of CSR by adopting theoretical perspectives and methods from the domains of organizational behavior, industry psychology, and HRM (e.g., Morgeson et al. 2013; Andersson et al. 2013; Renwick et al. 2016). The reason for this renewed interest is that the success of corporate sustainability initiatives largely depends on employee behaviors above and beyond formal organizational systems, policies, and programs. Understanding the individual motivations, emotions, attitudes, and socio-psychological mechanisms, and how all of them are linked to broader CSR outcomes have the potential to enhance our knowledge on corporate sustainability.

The benefits for examining micro foundations of CSR and employee sustainability behaviors can be summarized as follows: First, it makes it clearer why and how certain sustainability outcomes emerge in an organization (e.g., Glavas 2016; Strauss et al. 2017). Second, it provides valuable insights about how to conceptualize and measure employee- and team-based CSR activities (e.g., Ciocirlan 2017; Paille and Boiral 2013). Third, through these investigations companies might gain valuable insights on how to foster employee engagement in strategic CSR and sustainability practices of the organization (e.g., Lamm et al. 2015; Dumont et al. 2017; Kim et al. 2017). Finally, it can point out existing limitations and challenges regarding how to integrate sustainability principles and plans to daily work life (e.g., Strauss et al. 2017).

The Nature of Employee Sustainability Behaviors

Recent interest on ESB originates from a set of underlying factors. First, new and enhanced CS positions of firms mostly depend on individual champions questioning the status quo and advancing promoting sustainability initiatives. These champions are often typical employees with high environmental sensitivities who strive to bring a change toward sustainability in organizational outputs and processes. Related to this, the advance of various sustainability initiatives in an organization often arises as a result of employees' innovative ideas and suggestions. Most sustainability goals and strategies require direct and continuous involvement of employees in implementation and maintenance (e.g., diagnosis, documentations, controls, corrections) (Boiral and Paillé 2012).

In recent years, a number of different concepts have been offered to assess employee sustainability attitudes and behaviors at workplace. One noticeable construct is employee "green" or pro-environmental behavior, which refers to employees' engagement in visible actions and behaviors that are associated with and contribute to environmental sustainability (Ramus and Killmer 2007; Paille and Boiral 2013). Encouraging pro-environmental employee behaviors has become an essential part of creating a green workplace and an environmentally responsible organization (Renwick et al. 2016). Example green behaviors include saving electricity and other resources, avoiding waste, recycling office materials, and limiting paper printing.

Perhaps, the most widely discussed and surveyed employee sustainability behavior is organizational citizenship behavior for the environment (OCBE). It can be defined as employees' voluntary extra-role behaviors that are not explicitly acknowledged or rewarded, yet contribute to both mutual prosperity and organizational effectiveness regarding environmental issues (Boiral and Paillé 2012; Ramus and Killmer 2007). Corporate green initiatives are usually complex and time-consuming, thus it is difficult to fit them completely into formal job descriptions and work responsibilities. As voluntary extra-role

acts, OCBE include employee initiatives such as prioritizing environmental interests, suggestions, and initiatives aimed at reducing wastes, initiating sustainability programs, representing the organization at environment-related activities, engaging in environmental lobbying and activism, and collaborating with other departments to implement green technologies (Tosti-Kharas et al. 2017). In-role (required) environmental behaviors, however, are motivated by contributing to the core business such as adhering to organizational policies, changing work resources and methods, choosing responsible ones among given alternatives, and creating sustainable products. Because of their flexible, informal, and implicit nature, it is difficult to describe and measure OCBE accurately (Boiral and Paillé 2012). Nevertheless, certain measurements have been proposed and validated to analyze it.

Key Predictors of ESB

The answer to the fundamental question of what predicts ESB can be given regarding three types of antecedents: Individual factors, group and leadership factors, and organizational-level influences. Within the first type of predictors, personal values, similarity of these values with organizational values, pro-environmental attitudes and identity, concern with particular environmental and ethical issues and job factors typically shape employee commitment to CSR (e.g., Strauss et al. 2017; Norton et al. 2015). Values are deeply embedded in the decision-making process, thus they have a huge impact on how employees behave or willing to behave regarding environmental and social concerns (Tosti-Kharas et al. 2017). Evidence suggest that other factors including psychological and other development needs, self-efficacy beliefs, relational and moral motives as opposed to self-interest, collective self-esteem, prosocial identity, CSR knowledge and expertise (e.g., awareness of CSR guidelines, receiving CSR training), and long-term orientation are also associated with employee engagement in CSR (Aguinis and Glavas 2012; Strauss et al. 2017). Furthermore, perceived organizational support,

organizational commitment, and identification with the organization makes employees show stronger sustainability behaviors and encourage them to come up with creative sustainability ideas (Temminck et al. 2015; Tosti-Kharas et al. 2017).

Besides such individual influences, a second category of predictors reflect how leadership style, leader values, relationship with the leader, and group-level dynamics inform ESB. Research findings show that transformational leadership, responsible and ethical leadership style, commitment of the leader to CSR, and leaders' workplace sustainability behaviors are meaningfully linked to employees' sustainability concerns and behaviors (e.g., Robertson and Barling 2013; Renwick et al. 2016; Kim et al. 2017). Besides direct effects, leadership may also encourage ESB indirectly, in a combination with employees' own motivation and attitudes and through group dynamics. Hence, the work groups' sustainability beliefs and behaviors such as green advocacy do not only determine ESB alone but it also facilitates the impact of leadership (Kim et al. 2017).

The third type of predictors includes organizational-level influences, which shape voluntary sustainability behaviors at work. Studies show that organizational culture, organizational values, norms and practices toward sustainability, corporate environmental rules and practice, green HR policies, suggestion systems, and cross-functional communication can meaningfully improve ESB (e.g., Renwick et al. 2016; Temminck et al. 2015; Strauss et al. 2017; Morgeson et al. 2013). Such organizational dimensions trigger particular cognitive and emotional motives within the employee via highlighting the importance of context, capacity, and conditions for ethical conduct. Positive organizational factors also reduce the complications of sustainability for employees. For instance, the perception of support from the organization on sustainability issues make employees more committed and satisfied, leading to higher engagement in sustainability behaviors (Paille and Boiral 2013). Organizational climate also plays a significant role in fostering ESB. A pro-environmental (green) climate or an ethical climate can generate a caring and supportive

environment which stimulates employee involvement in sustainability behaviors.

It is worth noting that usually these three types of predictors influence ESB in an interactive manner. Thus, multilayer and multilevel models combining individual, group, and organizational level aspects provide a better and more realistic explanation of how ESB emerges and inspired within organizations.

Underlying Mechanism of ESB

Even though the existing knowledge on CSR mechanisms is limited, a number of models have been offered on the topic. For instance, Bolton and her colleagues (2011) found that CSR operates as a dynamic process which is composed of initiation, implementation, and maturation stages. The main CSR issues vary according to the nature of each step. In the early stages, there is no focus on the employees, neither as an essential stakeholder nor as an active participant in related initiatives. Arguments are limited to what CSR is and why it is required. Yet, as soon as implementation phase comes, employee involvement becomes evident and their internal stakeholder position is recognized. Employee contributions are observed most clearly when companies start to measure and evaluate CSR outcomes in the stage of maturation. This is because CSR engagement deeply affects employee attitudes, turning them into promoters of the organization's CSR activities. Overall, each and every phase of CSR development in an organization entails the involvement of employees coupled with a specific set of issues.

Aside such generic processes, organizational influences often translate their impact on ESB through socio-psychological mechanisms (Carmeli et al. 2017). Collectively held attributes such as care, altruism, honesty, ethical conduct, justice, and environmental sensitivity as well as the policies and structures built on such attributes in an organization make existing employees and newcomers more attracted to the organization, psychologically empowered, satisfied, and committed. In turn, employees become more willing to engage in sustainability behaviors. Thus, the

influence of contextual factors on ESB unfolds through the emergence of certain attitudes and affective reactions.

Some factors may also insert a conditional effect on all aforementioned relationships. Research findings suggest that supervisor commitment to ethics, trust in manager/supervisor, psychological contract, employee discretion, and issue salience can reinforce the relationships among individual and organizational predictors, employees' engagement in sustainability, and organizational outcomes (Paille and Boiral 2013). Additionally, some influences on ESB are conditional upon different leader (e.g., leadership style, leader's sustainability behaviors and attitudes) and team characteristics (e.g., team composition, norms, activities) (Norton et al. 2015).

Contributions to Individual and Organizational Outcomes

If employees work for a socially responsible company and participate in the organization's sustainability practices, their work engagement, perceived task significance, and in-role performance typically increase. Similarly, ESB is likely to improve employees' job satisfaction, sense of belongingness, commitment, and engagement in the work environment as well as their relationships with other organizational members (Aguinis and Glavas 2012; Carmeli et al. 2017). Besides, ECB has the potential to facilitate employee capability development, job performance, and creative output. ECB is also one of the key success factors of corporate sustainability as several studies display significant relationship between ESB and organization's environmental performance, reduced environmental impact, and effective organizational greening initiatives (e.g., Kim et al. 2017; Andersson et al. 2013). Additionally, sustainable dynamic capabilities of an organization are partly established by individual members' behaviors and characteristics such as adaptivity, proactivity, and pro-environmental attitudes (Strauss et al. 2017). Thus, corporate

sustainability performance as a whole is largely affected by individual sustainability actions (Ciocirlan 2017). One can also claim that extra-role behaviors of sustainability will eventually translate into stronger in-role behaviors where the issue of sustainability becomes a common way of thinking for employees.

Summary

The existing knowledge and recent research findings suggest that employee sustainability behavior is a new yet important phenomenon helping to understand how sustainability at individual-level emerges and develops within organizations, and what type of consequences it creates. As such, there have been increasing calls to both researchers and practitioners of CSR to integrate individual-level investigations of sustainability mechanisms and their results into strategic CSR thinking and initiatives. An ideal approach might be developing a multilevel and multidimensional framework where ESB is conceptualized as a product of an interface among individual employees, work groups, and organizational systems. Such a framework could provide precious information for evaluating the role of complex psychological, social and economic dynamics, and their interactions that produce ESB in organizations, which in turn promotes business sustainability.

With respect to practical implementations, companies have to fathom how to connect employee values, attitudes, and behaviors toward sustainability with ongoing job responsibilities and business operations. A couple of suggestions may include aligning employee and organizational values, clearly defining organizational long-term goals, making an economic and feasible case for sustainability, supporting sustainability champions in the organization, developing a sustainable knowledge and capabilities inventory, making sustainability initiatives more visible, and designing sustainable strategies with the involvement of employees.

Civil engagement; Employer supported volunteering; Helping activities; Skill-based volunteering programs; Volunteerism management

Definition

The idea of volunteering can be classified as a form of helping behavior where people, and volunteers, willingly devote and commit themselves to nonfinancially rewarded activities, especially in the third sector. Considering that organizations in the third sector are driven by the desire to contribute and achieve social goals, they mostly rely on volunteers to undertake most of their activities. Many factors such as unsustainable cost structure, lack of requisite skills, unemployment, and underemployment are influencing organizations, especially in the third sector to rely more on volunteers. Under the UK employment law such as Equality Act 2010 and the Employment Rights Act 1996, volunteers are not recognized as employees and not protected, undermining their contributions in enhancing social and economic prosperities of their community.

However, many organizations are now incorporating volunteering, in the form of employee volunteer programs (EVP), into their learning and development activities to enhance their reputation and engage with the local community. Despite its perceived benefits, the true social and economic impacts of EVP on the community, host organizations, parent organizations, and volunteers including its motivations should be sufficiently explored to establish how EVP can be integrated into the organization's strategy. With the increasing popularity of volunteering in most western countries, particularly in the UK, there should be more clarity about its motivations and value-creating capabilities to local and national economies. This entry, therefore, analyzes EVP, its benefits, and key issues for organizations and volunteers to make informed decisions about the implementation of EVP.

Introduction

Organizations engage with stakeholders, internal and external, through different mechanisms such as employee training and development, engaging in philanthropic activities, to improve their reputation and competitiveness. In recent times, organizations worldwide are showing increasing

interest in employee volunteer programs (EVP) also known as employer supported volunteering (ESV). Their intention is to enhance the reputation of organizations and provide opportunities for their employees to acquire more skills by undertaking unpaid volunteering activities during the work hour. With resource constraints, especially financial, the contributions of volunteers, particularly to organizations in the third sector, cannot be overemphasized. Many not-for-profit organizations rely on the pool of volunteers to facilitate their activities (Erks et al., 2021).

While volunteering is not new, with many people participating in unpaid activities in their free time, EVP is construed as a mechanism for organizations to support their employees by providing opportunities to participate in volunteering activities during work hours (Chartered Institute of Personnel and Development (CIPD), 2022). This concept is increasingly gaining traction across different sectors, especially in the third sector, due to its perceived benefits in enhancing organizations' social responsibility (Howard & Serviss, 2022) and contributions to employees' skills development (CIPD, 2022). According to Erks et al. (2021), volunteering offers benefits to non-profit (or host) organizations, parent organizations, volunteers, and the society in general.

Providing these opportunities, especially to full-time employees during work hours, is important due to time constraints and work pressure/demand, preventing many full-time employees from engaging in volunteering activities of their choice. Although there are perceived overt benefits from EVP, there are many ethical and moral issues that should be addressed to understand why organizations and employees elect to engage in volunteering activities. There is also the need to understand the impacts of EVP on colleagues who are not volunteering but must take extra job responsibilities when volunteers are away, especially in result-driven and goal-oriented organizations. EVP is expected to involve nonfinancially paid activities; it is not clear whether there are other work-based incentives and reward systems motivating employees to undertake volunteering activities. It is equally important to establish whether volunteering activities/programs represent the

interest of recipients, or they are another sideshow from organizations to distract stakeholders from key social and environmental issues associated with their operations.

Irrespective of its motivations and goals, there is evidence to suggest that EVP represents an opportunity for organizations and their employees to meet societal needs through nonfinancially rewarded activities. Despite the reported benefits in the literature, there is a need for more empirical evidence on practicality of EVP and whether volunteering activities during work hours make any real impacts. This argument echoes Erks et al.'s (2021) observation that studies have not sufficiently explored the benefits of EVP, especially to profit-making organizations that promote volunteering activities or employ volunteers. The purpose of this entry is to instigate debate about EVP by drawing scholars and practitioners' attention to many issues associated with EVP while challenging the dominant school of thoughts about its benefits. This debate should instigate evidence-based research on the governance and impacts on EVP and provide meaningful insights into how impactful volunteer programs can be designed and implemented.

Understanding EVP: Theoretical Perspectives

Studies (such as Erks et al., 2021; Howard & Serviss, 2022) have shown that EVP is underpinned by disparate of personal, psychological, and contextual factors. These factors are intrinsic and extrinsic, indicating that EVP is behavioral and can be examined using social-psychology theories. These theories include organizational citizenship behavior (Organ, 1997) and social exchange theory based on Gouldner's (1960) idea of reciprocity.

Organizational citizenship is construed as a concept often adopted whereby employees including managers are perceived as citizens (akin to citizens of a country) with duties or responsibilities beyond their formal contractual (or role-based) obligations. Organizational citizenship behaviors (OCB) are non-role-related

behaviors but contribute to the effective functioning of the organization. These behaviors can be broadly classified into altruism and generalized compliance dimensions. Based on their altruism dimension, OCB are employees' voluntary engagement or participation in organizations' activities and motivated to a larger extent by individual employee's internal disposition.

Contrary to OCB, social exchange theory (SET) posits that people continuously evaluate costs and benefits of their actions as a means of interacting with their society and environment. The theory places emphasis on motives to explain why two people or organizations enter a relationship while others may not. The theory resonates with the idea that people are rational in their thought process, always seeking to maximize rewards and minimize the associated costs. The cost-benefit analysis and its outcomes determine whether an individual will undertake an action or perform the focal behavior. Although EVP constitutes voluntary activities, SET proposes that employees may decide not to participate in a volunteering program if its perceived costs outweigh the perceived benefits.

On the other hand, employees may be obliged to participate in a volunteering program if the program is initiated by their employer because of the influence of psychological contract on their behavior. The psychological contract can play a role in employee's behavior considering that employees' perceptions of their employer's expectations are mostly inaccurate and imprecise. Employees' behavior and their relationship with their employers are influenced by many implicit assumptions and expectations, forcing many employees to act beyond their formal contractual obligations to demonstrate their commitment. These assumptions and the expectations that employees can be rewarded by their employer through the organizational formal reward systems and opportunities, such as promotion and salary increase, may influence and contribute to employees' participation in EVP. Using this perspective, EVP is transactional, with employees expecting some forms of reward or compensation for their engagement in EVP within and outside the organization.

Key Issues

Although OCB has received many criticisms for its ambiguities (Organ, 1997) and is perceived to be conceptually misguided, the construct is attracting increasing interests from different scholars in various academic disciplines (Organ, 2018; Podsakoff et al., 2000). For example, Appelbaum et al. (2004) and Tsai and Wu (2010) investigated OCB using employees in Canada and Taiwan, respectively. According to Tsai and Wu (2010), the relationship between employees' job satisfaction and OCB among Nurses in Taiwan was observed to be positively significant. In other words, employees could feel a sense of belonging to organizations and perform discretionary roles that are not specified by their contractual roles when they are satisfied with their jobs including the work environment. This suggests that the propensity of employees to commit and be loyal to their organization and hence perform discretionary duties is strong when there is a perception of strong satisfaction about their jobs. This argument aligns with Licandro et al.'s (2022) observation that volunteer's satisfaction contributes positively to permanence in volunteering activities; however, they further reported that other factors, such as demographics including the level of education, influence the effects.

It should be noted that job satisfaction is subjective and attracts different interpretations that may exert inconsistent effects or relationships with citizenship behaviors as seen in many studies. For example, an employee may be satisfied with their employer/organization if there is an opportunity to volunteer outside the organization during work hours; however, another employee from the same organization may perceive no satisfaction if they undertake additional responsibilities due to colleagues undertaking EVP outside the organization (or formal job functions).

This hypothetical example suggests that employees may be generally satisfied when their personal needs are met by their employer which aligns with SET and can be construed as a form of egoistic behavior in some instances. Although job satisfaction is operationalized as antecedent of OCB, the explanation why people perceive job

Employee Volunteer Programs, Fig. 1 Conceptualizing motivations for Employee Volunteer Programs (EVP)

satisfaction is situational and subjective/personal and its effects on OCB can be mediated or moderated by culture (for instance, organizational culture and societal culture) and people's perceptions and values. For a better explanation of EVP from OCB standpoints, motivations for engaging in EVP represent disparate factors at opposite ends of a continuum rather than a distinct construct (Fig. 1).

On the one side of the continuum are egoistic motivations, and at the other extreme end are altruistic motivations with most people situated in between these two extremes. Based on this model (Fig. 1), what is perceived as volunteering activity may not be entirely voluntary, unpaid, and/or discretionary as there may be nonfinancial rewards or incentives, such as personal fulfilment and satisfaction, for participating in EVP. The main argument is that EVP is not entirely voluntary and non-rewarded, and self-interest contributes to why employees engage in EVP, although the influence of egoism can be subtle.

The nature of EVP including its impacts on the recipients and whether it allows the volunteer to apply their skills and develop new skills should be further examined to establish its true benefits. Also, how it is perceived by others within an organization, especially those who are not participating in EVP but must be responsible for additional tasks that contribute to the effectiveness and productivity of their organization. This chapter is not undermining EVP and argues that EVP can benefit an organization and its employees which on the aggregate may contribute to efficiency and effectiveness of the organization. However, the true costs of EVP on all stakeholders should be further explored and established. Consistent with Williams and Anderson (1991), this chapter

concludes that EVP can be directed toward individuals (OCB-I) and/or organizations (OCB-O). In many organizations, OCB-I and OCB-O are the two broad forms of helping behavior with OCB-I explaining helping behaviors rendered to colleagues and other individuals contrasting helping behavior toward the organization, OCB-O. Using the tenet of SET, OCB-O can be transactional, suggesting that employees might be expecting some form of incentives or rewards from undertaking OCB, for example, EVP, that contributes to the performance of the organization.

There should be more clarity about the constituents of EVP and who benefits from it including how it can be promoted in an organization. The key argument of this chapter is that the construct should be labeled skills-based volunteering program (SBVP), allowing employees to contribute their professional experience and skills to create value for the host organization while acquiring further skills that can enhance their employer/organization's effectiveness. According to Dempsey-Brench and Shantz's (2022) systematic literature review, employee skills-based volunteerism (ESBV) program is strategically driven and aligns with employee's skills, expertise, talents, and education to address the specific needs of host organizations. In other words, the needs of the target organization should be known before identifying and mapping the available relevant skill set, ensuring that employee's skills and expertise are matched with the organizational/strategic fit of the target organization. For any meaningful impacts and benefits, organizations introducing employee volunteer programs should co-create such programs with the target organization.

There could be challenges in designing and implementing employee volunteer programs without engaging with relevant stakeholders. This engagement is required because not all volunteering and discretionary programs would contribute to organizational effectiveness or be performed without any formal recognition of performance evaluation or reward system of an organization. While employees may decide to not/participate in the program, a fundamental question is whether volunteer programs that are underpinned by the organization's policies and/or

institutional requirements should be classified as voluntary/discretionary.

Nevertheless, EVP can be examined from OCB and SET perspectives and analyzed at institutional, organizational, leader, team, and employee levels for a better understanding of how EVP within an organization can be facilitated. Organizations should support their employees' voluntary initiatives and provide a mechanism on how the impacts from such programs could be realized to measure their effectiveness.

Summary

The popularity of EVP is increasing; however, this entry argues that more clarification about the constituents and impacts of EVP to stakeholders involved should be established. These clarifications are necessary considering CIPD's (2015) views that volunteering is traditionally linked to corporate social responsibility (CSR). However, organizations are now sensing the opportunity to introduce community-based volunteering programs to enhance their employees' development and the opportunity to connect with local communities.

On the one hand, it is important for organizations to analyze the effects of their operations on stakeholders and understand the needs of the stakeholders to effectively address the expectations/needs of recipient organizations through EVP. On the other hand, it is important for stakeholders, especially employees, to understand how their actions contribute to the effective functioning and productivity of their organization through voluntary and discretionary actions. While the former construed as CSR emphasizes the roles of organizations in the society beyond profit making (Moodaley & Telukdarie, 2023; Osobajo et al., 2022), the latter can be conceptualized as Organizational Citizenship Behavior (OCB) (Cheema et al., 2020; Organ, 1997), explaining roles of employees within an organization beyond their formal contractual obligations. The effects of EVP on colleagues who have not undertaken volunteering activities during work hours but

must undertake extra tasks should be further explored to establish the real impacts of EVP.

The main argument about EVP should demonstrate that organizational efficiency and performance are most likely due to some employees' actions and behavior, in/directly, that are beyond their formal job descriptions and rewards. Although these actions are supposed to be non-rewarded by the organization's formal reward systems, EVP, such as street cleaning and working in a charity shop, should be assessed based on its impacts on organizational efficiency and contributions in developing employees' skills and expertise. Organizations and employees should focus on skills-based volunteering programs instead of activities that add no value to host organizations and volunteers.

Employer Brand Management

► Employer Branding

Employer Branding

Katarzyna Klimkiewicz

Faculty of Management, AGH University of
Science and Technology, Cracow, Poland

Synonyms

Employer brand management; External branding;
Internal branding; Internal marketing

Definition

Drawing from relationship marketing, Ambler and Barrow (1996) define employer brand as “the package of functional, economic and psychological benefits provided by employment and identified with the employing company” (Ambler and Barrow 1996, p. 187). Employer brand offers a value proposition for employees. It is aimed at differentiating and promoting the employer’s offer to attract new employees and maintain current employees. It may be developed based on different sets of values; however, it is important that the value proposition offered by the employer brand reflects the values embedded in the organizational culture. In turn, Miles and Mangold (2004) define employer branding (EB) as a “process by which employees internalize the desired brand image and are motivated to project the image to customers and other organizational constituents” (Miles and Mangold 2004, p. 67). By influencing individual behavior, employer branding will impact corporate performance and may be important for gaining a competitive advantage. It may be stated that building EB is oriented toward attracting candidates who will identify with the stated values and share them among customers (Foster et al. 2010; Heskett 1987). This assumption is well demonstrated by Ambler and Barrow who cite a leading retailer among their respondents: “if we have the best shops, with the best people, then we have the best word of mouth and

receive the best applications and then we will have the best shops” (Ambler and Barrow 1996, p. 186).

While defining employer branding, Sullivan (2004) states that it is “a targeted, long-term strategy to manage the awareness and perceptions of employees, potential employees, and related stakeholders with regards to a particular firm.” According to the Chartered Institute of Personnel and Development (CIPD), employer branding is a “set of attributes - often intangible – that makes an organization distinctive, promises a particular kind of employment experience, and appeals to those people who will thrive and perform to their best in its culture” (Walker and Higgins 2007, p. 3). Some researchers maintain that employer branding only refers to activities directed toward the external labor market (job applicants), while relations with employees constitute internal marketing or internal branding (Foster et al., 2010; Wilden et al. 2010).

Introduction

Due to increased competition on the labor market and difficulties in attracting qualified employees, enterprises must undertake activities to build their brand. Millennials particularly, with their sensitivities toward ethical issues, are encouraging firms to present their employer value propositions, including social and environmental responsibility, sustainability, corporate citizenship, etc. An employer brand (the so-called brand of “employer of choice”) is aimed at attracting a new workforce, retaining current employees, and reducing recruitment process costs by consolidating awareness of market participants in that brand.

The concept of employer branding (EB) emerged from research, where marketing tools were adapted to the employment context (Martin et al. 2005). Ambler and Barrow (1996) proposed transferring the traditional notion of marketing, based on the assumption of short-term transactional economics, to a more people-oriented model. They stated that “continuing good

relationships between the company and its customers necessarily involves the employees” (Ambler and Barrow 1996, p. 185). The authors proposed joining the separate disciplines of human resource management (HRM) and brand marketing into a single, conceptual framework. HRM stresses that people are the most important *resources* of the organization; however, in reality, organizational and employee interests might not be aligned. HRM was criticized, therefore, for ignoring the individual’s expectations and attitudes and accused of manipulative and unfair practices (Storey 1995). From the perspective of internal marketing, employees are considered to be *subjects* of company activities. By considering employees as internal clients, employer branding seeks to make an analogy of company-customer relations and link it to HRM. Organizations invest in promoting their products and services to their customers, building a corporate image so customers can identify with it and be loyal. Employer branding proposes to use a similar approach to managing relations with current and prospective employees.

Defining employer branding requires, however, distinguishing it from other familiar concepts linked to the employer’s image, identity, and reputation. In fact, companies have a set of

different images, including, e.g., the market image linked to the perception of the products and services offered by the company, the financial image that reflects the perceptions about financial performance, and the social image that refers to how the company is perceived in terms of its social performance and corporate social responsibility. Employer image is thus part of a broader framework of organizational image and refers to how the company is perceived as a place to work (Highhouse et al. 2009).

The term *employer brand* comes from HR practice and duplicates, to some extent, the concept of employer image. Lievens and Slaughter (2016) ask not to create any new concepts but to link to existing ones. They posit that the external employer brand refers to the organization’s employer image, while the internal employer brand corresponds to the organization’s identity. Respectively, external employer branding is considered a synonym for employer image management, and internal employer branding refers to identity management (Lievens and Slaughter 2016). However, due to the popularity of the term *employer branding* (Fig. 1) in both academia and HR practice, it is worthwhile to provide a systemic overview of its features.

Employer Branding, Fig. 1 The popularity of the terms employer brand, employer image, and employer identity from 2004 to 2018 (This graph was created with Google Trends. According to Google Trends graphical design, the numbers at the vertical axis (0–120) represent individual

interests in the search for the highest point on the graph. A value of 100 indicates the highest popularity of the password. A value of 50 indicates the password was half as popular. A value of 0 indicates that there is not enough data for the given password)

Internal and External Employer Branding

While marketing addresses its activities primarily toward customers, building an employer brand requires distinct activities aimed at two main groups of recipients: internal, current employees of the company and external, potential candidates who might be willing to apply for a job. According to this differentiation, two types of activities can be distinguished: [1] external branding, which is aimed at building the employer brand on the external labor market to increase the possibility of acquiring the best candidates by forming appropriate associations with the employer's brand, and [2] internal branding, which is aimed at shaping the company image among current employees, binding them to a given workplace, and increasing their satisfaction in this particular workplace.

Referring to **external employer branding**, Backhaus and Tikoo (2004) note that – similar to the customer decision-making process, which considers features of products or services – job applicants consider features of the job offer that, in their opinion, are linked to the employment relationship (Backhaus and Tikoo 2004).

According to Lievens and Highhouse (2003), the employer value proposition consists of two features: instrumental and symbolic. Instrumental features are concerned with objective, physical, and tangible attributes, such as working conditions, type of employment contract, work hours, vacations, rewards, and development opportunities. Symbolic features refer to subjective, abstract, and intangible attributes, such as perceived prestige, reputation, feeling of belonging, and appreciation (Lievens and Highhouse 2003). The symbolic characteristics help to create employer identity and differentiate and enhance the company's effectiveness in retaining the current workforce and attracting new employees. Both the subjective and objective aspects may vary according to the expected psychological contract (Backhaus and Tikoo 2004; Miles and Mangold 2004). The external employer brand is communicated through formal sources of communication, such as PR/marketing communication,

communication regarding employment issues and the recruitment process, and informal sources, such as employee recommendations and other applicant opinions on the recruitment process. Finally, the candidate arrives at a personal understanding of the employer brand based on personal experience with the recruitment process, communication processes, and the organizational culture.

Internal branding is often defined as the use of marketing tools to increase employee motivation and satisfaction, which are then expected to lead to increased satisfaction of external customers. The internal employer brand depends on employee experience with the organization's management systems, HR practices, procedures, organizational structure, and culture. The adoption of organizational values is, therefore, associated with increased employee identification with the organization and their involvement in the implementation of the stated organizational goals. Employees are perceived as internal clients, whose engagement and commitment help to spread the positive image of the company and build relations with customers, based on trust (Rafiq and Ahmed 2000). As the relationship between employee and employer is of a contractual nature, it is assumed that, regardless of different types of psychological contracts, the perceived commitment of the employer to fulfill its part of the contract influences employee engagement and satisfaction. With any violation of the psychological contract, the employer loses credibility. Reasons for an employer violating the psychological contract may vary, but the result may be an internal withdrawal, a decrease in engagement, loss of loyalty, or even leaving the job (Morrison and Robinson 1997).

Substantial Theories Behind the Employer Brand

The marketing literature provides two perspectives for understanding how brands work: [1] the brand may be viewed as a plan for decision-making that offers the consumer a choice, or [2] the brand may be viewed as a construct that may include symbolic meanings. Two different types

of associations may thus emerge for the consumer: the product may be seen as having functional-rational benefits, or the benefits may be perceived as symbolic or emotional. When the consumer chooses a product based on an analysis of the product's functional benefits, the decision is a rational one. If the consumer places more value on the attributes attributed to the product, the decision is more likely to be an emotional one. Backhaus and Tikoo (2004) note that, during recruitment, job candidates consider both the functional and symbolic benefits they perceive as related to the job. Functional benefits refer to the aspects related to the type of employment contract, working conditions, wages, working time, or holidays (aspects of an objective nature). Symbolic benefits refer to the perceived image, prestige, or social benefits resulting from working in a particular organization, such as recognition or affiliation.

Marketing literature assumes that the purchase of goods reflects the consumer's world view, identity, and lifestyle. In turn, recruitment literature provides three main theoretical explanations for how the employer brand works. According to the **person-organization fit**, candidates are assumed to make a comparison between their needs, traits, and values and what the employer brand represents. Candidates tend to choose an employer whose values are more in line with the candidate's world view (Cable and Judge 1996). The value fit explains why some applicants are particularly attracted to organizations which build their brand based on values that are important to job seekers. The theory of **social identity** (Ashforth and Mael 1989; Tajfel and Turner 1979) and **organizational identity theory** (Dutton et al. 1994) state that organizations may become an important part of employee self-concept and social identity. Social identity theory explains the relationship among the group's individuality and its self-assessment, e.g., employees from one team perceive themselves as an integrated and effective group versus other teams, which they perceive as less effective. It is assumed here that an individual's choice of a given organization reflects a positive self-view resulting from a sense of community with that organization. A positive

perception of an employer's brand makes a prospective employee more interested in identifying with and becoming a member of this particular organization (Backhaus and Tikoo 2004).

Additionally, the **signaling mechanism** (Rynes 1991) is used to analyze the behavior of job candidates who do not have direct experience with the organization. It is assumed that candidates interpret the results of the organization's activities, as well as information provided in the recruitment process, as signals that the organization possesses certain characteristics (e.g., the company cares for employees, is a leader in the industry, offers development opportunities). Commitment to stakeholders is interpreted as a potential signal that employees in a given organization will be treated well (Rupp and Mallory 2015). Similarly, signals that an organization is committed to environmental protection and conducts anti-discrimination or pro-social policies are associated with the intentions of job candidates who are more likely to work in an engaged organization or who, already as employees, are proud of the fact that the organization's activities correspond with their personal values (Greening and Turban 2000; Gully et al. 2013; Jones et al. 2014).

CSR-Based Employer Branding

Recent studies confirm that millennials are sensitive toward ethical issues (Howe and Strauss 2000). Millennials often indicate that they expect their future employer to demonstrate social responsibility, going beyond the regular economic context and narrow organizational interests.

Corporate social responsibility (CSR) is becoming an important element of employer branding communication. A range of studies point at a positive link between CSR and organizational reputation (Greening and Turban 2000; Backhaus et al. 2002) supporting the idea that job seekers are more likely to accept a job offer from a firm they consider to be socially responsible rather than from one with a poor CSR reputation (Behrend et al. 2009; Alniacik et al. 2011; Tsai et al. 2014). Klimkiewicz and Oltra (2017) propose, however, that it is not the specific content of

CSR communication that attracts job seekers, but rather their individual attitudes toward CSR and need for social recognition and identification. Based on a sample of millennial job seekers highly sensitive toward ethical issues, the authors show that only respondents with positive attitudes toward CSR were attracted to the CSR-based employer image, while respondents who were skeptical about the concept of CSR were less inclined to apply for a job with an employer considered to be socially responsible (Klimkiewicz and Oltra 2017).

Practical Aspects of Building the Employer Brand

The concept of employer brand refers to the company's pursuit of a balanced strategy on the labor market, recruiting employees, fostering ties between these employees and the company, motivating employees to demonstrate desired behaviors, building an organizational culture, and shaping the image of the employer. The core values of the employer brand are as follows (Fig. 2):

1. Creating an attractive value proposition refers to the set of symbolic attributes that should enhance employer brand awareness and image, work to build the corporate reputation, and be consistent with the organization's identity and culture. The value proposition can be developed based on different sources, such as organizational culture and values, preferred leadership style, insights taken from employee

surveys, critical assessment of the perceptions of the current image, and analysis of labor market expectations.

2. Considering the perspective of current employees requires assuring that the value proposition meets expectations. As employees assess employer attractiveness, their current experience with functional benefits offered in the employment relationship plays an important role. Safe working conditions, supportive environment, fair compensation, and training and development opportunities create the basis for employees determining that the employer meets their expectations and fulfills its part of the contract. Symbolic attributes may be introduced through the organization's culture, declarations, and statements, as well as through internal and external communication. Internal communication should ensure awareness of the brand among employees, as well as give them the possibility of participating in the continuous improvement process of the organization. Firms often encourage employees to tell stories about their experiences with the company. This builds commitment and loyalty among employees and increases trust.
3. Considering the employee perspective refers to building the prestige of the organization and increasing employer attractiveness. The determined value proposition may be marketed toward an external audience, such as prospective employees, headhunters, or recruiting agencies. The organization actively uses various channels to reach candidates and become the "employer of choice," first within the recruitment process via job advertisements,

Employer Branding, Fig. 2 The employer branding process

information on the website, recruiting portals, social media, job fairs, and materials for applicants, and second, within the selection process. A well-organized recruitment and selection process, professional staff, the setting where interviews are conducted, constructive feedback, and respect shown to all candidates – these are some examples of activities that impact the employer brand shared from candidate to candidate through word of mouth.

As with every investment, the employer brand requires systemic monitoring and assessment. The most common metrics used to measure the impact of the employer brand are based on employer league table rankings, such as Universum, “Great Place to Work,” employee turnover, and costs per hire. Analyzing the employer brand, however, requires going behind the recruitment metrics to consider measures of internal brand perception and engagement (Mosley 2014).

The literature reveals a range of propositions for constructing a scale for measuring the employer brand. Ambler and Barrow (1996) propose including three dimensions: functional, economic, and psychological. Highhouse, Lievens

and Sinar (2003) suggest measuring organizational attractiveness by assessing company attractiveness, intentions to pursue a job offer, and prestige. More extended scales refer to aspects such as development, application, and economic and social interest (Berthon et al. 2005); carrying, enabling, career growth, credibility and fairness, flexibility and ethical values, image of product and service brand, positive employer image, and global exposure (Srivastava and Bhatnagar 2010); and task, team, internationality, reputation, benefits, development, work-life balance, culture, diversity, and job security (Hillebrandt 2013). This variety of employer brand measurement scales reflects the crucial aspects of building effective employer brands.

A comprehensive framework for understanding employer branding proposed by Mosely (2014) differentiates the key employer brand measurements into three categories: [1] process efficiency and effectiveness, [2] brand reputation and experience, and [3] desired behaviors and outcomes. The author also indicates measures for assessing both internal and external impacts on process effectiveness and performance, communication, and individual satisfaction (Fig. 3).

Employer Branding, Fig. 3 Key employer brand measures (Source: Based on: (Mosley 2014))

Summary

The concept of employer brand responds to the current challenges of communication on the labor market. This approach should be in line with the current CSR approach, as adoption of marketing tools in the HRM field prompts companies to recognize their employees as internal clients, crucial for the company's success. In turn, CSR may be a part of employer branding used as a value proposition to attract employees. Additionally, employer branding encourages firms to take an analytical approach by capturing data to assess the internal and external workforce, as well as the effectiveness of HR processes and communication. Monitoring the employer brand also requires linking the determined EB metrics into desired outcomes and behaviors. This allows for a more comprehensive linkage between the organization's strategic orientation and human capital management.

Employment involvement

Definition

Employee engagement has been defined in many different ways. Most often it has been defined as emotional and intellectual commitment to the organization (Baumruk 2004; Richman 2006; Shaw 2005) or the amount of discretionary effort exhibited by employees in their jobs (Frank et al. 2004).

In the academic literature, a number of definitions have been provided. Kahn (1990, p. 694) defines personal engagement as “the harnessing of organization members’ selves to their work roles; in engagement, people employ and express themselves physically, cognitively, and emotionally during role performances.” Thus, engagement means to be psychologically present when occupying and performing an organizational role.

It has been also defined as psychological presence but he goes further to state that it involves two critical components: attention and absorption.

Schaufeli et al. (2002) define engagement “as a positive, fulfilling, work-related state of mind that is characterized by vigor, dedication, and absorption.” They further state that engagement is not a momentary and specific state, but rather it is “a more persistent and pervasive affective-cognitive state that is not focused on any particular object, event, individual, or behavior.”

Introduction

Employment engagement has become an important topic in recent years even if it has rarely been studied in the academic literature and relatively little is known about its antecedents and consequences.

Most of what has been written about employee engagement can be found in practitioner journals where it has its basis in practice rather than theory and empirical research.

The notion of “employment engagement” is quite similar to other notions in the organizations but with some differences.

Organizational commitment differs from engagement in that it refers to a person’s attitude and attachment toward their organization. Engagement is not an attitude; it is the degree to which an individual is attentive and absorbed in the performance of their roles. The focus of engagement is one’s formal role performance rather than extra-role and voluntary behavior.

Engagement also differs from job involvement. According to May et al. (2004), job involvement is the result of a cognitive judgment about the need-satisfying abilities of the job and is tied to one’s self-image. Engagement has to do with how individuals employ themselves in the performance of their job. Furthermore, engagement involves the active use of emotions and behaviors in addition to cognitions. May et al. (2004, p. 12) also suggest that “engagement may be thought of as an antecedent to job involvement in that individuals who experience deep engagement in their roles should come to identify with their jobs.”

In summary, although the definition and meaning of engagement in the practitioner literature often overlaps with other constructs, in the academic literature, it has been defined as a distinct and unique construct that consists of cognitive, emotional, and behavioral components that are associated with individual role performance. Furthermore, engagement is distinguishable from several related constructs, most notably organizational commitment, organizational citizenship behavior, and job involvement.

In literature, there are two streams of research that provide models of employee engagement. In his qualitative study on the psychological conditions of personal engagement and disengagement at work, Kahn (1990) interviewed summer camp counselors and organizational members of an architecture firm about their moments of engagement and disengagement at work. Kahn (1990) found that there were three psychological conditions associated with engagement or disengagement at work: meaningfulness, safety, and availability. In other words, workers were more engaged at work in situations that offered them more psychological meaningfulness and psychological safety and when they were more psychologically available.

In the study to empirically test Kahn’s (1990) model, May et al. (2004) found that meaningfulness, safety, and availability were significantly related to engagement. They also found that job enrichment and role fit were positive predictors of meaningfulness; rewarding co-worker and supportive supervisor relations were positive predictors of safety while adherence to co-worker norms and self-consciousness were negative predictors; and resources available were a positive predictor of psychological availability while participation in outside activities was a negative predictor. The other model of engagement comes from the burnout literature which describes job engagement as the positive antithesis of burnout noting that burnout involves the erosion of engagement with one’s job (Maslach et al. 2001). According to Maslach et al. (2001), six areas of work-life lead to burnout and engagement: workload, control, rewards and recognition, community and social support, perceived fairness, and values. They argue that job

engagement is associated with a sustainable workload, feelings of choice and control, appropriate recognition and reward, a supportive work community, fairness and justice, and meaningful and valued work. Like burnout, engagement is expected to mediate the link between these six work-life factors and various work outcomes. Although both Kahn's (1990) and Maslach et al.'s (2001) models indicate the psychological conditions or antecedents that are necessary for engagement, they do not fully explain why individuals will respond to these conditions with varying degrees of engagement. A stronger theoretical rationale for explaining employee engagement can be found in social exchange theory (SET). SET argues that obligations are generated through a series of interactions between parties who are in a state of reciprocal interdependence. A basic tenet of SET is that relationships evolve over time into trusting, loyal, and mutual commitments as long as the parties abide by certain "rules" of exchange (Cropanzano and Mitchell 2005).

Rules of exchange usually involve reciprocity or repayment rules such that the actions of one party lead to a response or actions by the other party. For example, when individuals receive economic and socioemotional resources from their organization, they feel obliged to respond in kind and repay the organization (Cropanzano and Mitchell 2005). This is consistent with Robinson et al.'s (2004) description of engagement as a two-way relationship between the employer and employee.

One way for individuals to repay their organization is through their level of engagement. That is, employees will choose to engage themselves to varying degrees and in response to the resources they receive from their organization. Bringing oneself more fully into one's work roles and devoting greater amounts of cognitive, emotional, and physical resources is a very profound way for individuals to respond to an organization's actions. It is more difficult for employees to vary their levels of job performance given that performance is often evaluated and used as the basis for compensation and other administrative decisions. Thus, employees are more likely to exchange their engagement for

resources and benefits provided by their organization.

In summary, SET provides a theoretical foundation to explain why employees choose to become more or less engaged in their work and organization. The conditions of engagement in both Kahn's (1990) and Maslach et al.'s (2001) model can be considered economic and socio-emotional exchange resources within SCT. When employees receive these resources from their organization, they feel obliged to repay the organization with greater levels of engagement. In terms of Kahn's (1990) definition of engagement, employees feel obliged to bring themselves more deeply into their role performances as repayment for the resources they receive from their organization. When the organization fails to provide these resources, individuals are more likely to withdraw and disengage themselves from their roles. Thus, the amount of cognitive, emotional, and physical resources that an individual is prepared to devote in the performance of one's work roles is contingent on the economic and socio-emotional resources received from the organization.

Key Issue

Although there is little empirical research on the factors that predict employee engagement, it is possible to identify a number of potential antecedents from Kahn's (1990) and Maslach et al.'s (2001) model.

The driving force behind the popularity of employee engagement is that it has positive consequences for organizations. There is a general belief that there is a connection between employee engagement and business results (Harter et al. 2002).

The model of antecedents and consequences of employee engagement developed by Sacks (2006) is represented in the following Fig. 1:

He provides one of the first empirical tests of the antecedents and consequences of employee engagement.

Other works found that difference in skills and abilities and disposition variables have impact on

Employment Engagement, Fig. 1 The model of antecedents and consequences (Sacks 2006)

E

the levels of employee engagement. In the same direction, others found that gender difference, personal values, culture, and climate of organizations also influence employee engagement.

Future Directions

Employee engagement is a meaningful construct that is worthy of future research. There are several avenues to consider. One area would be to investigate other potential predictors of job and organization engagement. There are other variables that might also be important for both job and organization engagement. For example, human resource practices such as flexible work arrangements, training programs, and incentive compensation might also be important for engagement. Future research could include a broader range of predictors that are linked to particular types of role engagement. Along these lines, future research should attempt to flesh out the types of factors that are most important for engagement in different roles (e.g., job, organization, and group).

Future research might also consider individual difference variables that might predict employee engagement. Several personality variables including hardiness, self-esteem, and locus of control are related to burnout and might also be important for engagement (Maslach et al. 2001). Self-efficacy has also been recognized as an important factor in burnout and engagement (Maslach et al. 2001). There is also some evidence that individuals with a strong exchange ideology are more likely to feel obliged to reciprocate a benefit (Cropanzano and Mitchell 2005). Thus, the

relationship between various antecedents and engagement might be stronger for individuals with a strong exchange ideology. Future research might test the moderating effects of exchange ideology for the relationship between antecedents and engagement.

A final area for future research is to study the potential effect of experimental interventions on employee engagement. There is some evidence that exchange-inducing interventions can invoke a sense of obligation on the part of individuals who feel obliged to reciprocate (Ganzach et al. 2002). Thus, future research might investigate the extent to which interventions can create a sense of obligation that leads individuals to reciprocate with higher levels of engagement. For example, training managers to be more supportive might be effective for improving perceptions of organizational support and caring. Job design interventions that provide employees with more autonomy and variety in their work as well as career management interventions might also be effective.

This is likely to be a fruitful area for future research given the increasing interest on the part of organizations to improve employee engagement and address the so-called engagement gap.

- There is a meaningful distinction between job engagement and organization engagement.
- A number of antecedent variables predict job and organization engagement.
- Job and organization engagement are related to individual consequences.
- Job and organization engagement mediate the relationship between antecedent variables and consequences.

Definition

Conspicuous consumption is the notion that the key motivation behind consumer consumption behaviors is to signal wealth and status. It was initially proposed by Veblen in 1899. It theorizes that consumers display their wealth and position in the social hierarchy publicly through lavish expenditure on consumption, leisure activities, and services. Consumers distinguish themselves from those who are in lower social classes through conspicuous consumption. The theory was proposed to explain the evolution of a leisure class in the USA. Veblen argued that as the working class started to generate wealth, members of the leisure class, who do not work but depend on income from the working class, signal their superior position in the social hierarchy through private property, extensive leisure activities, and lavish consumption. The key to emphasizing superiority is to waste more money than is necessary. Over time the focus on leisure activities reduced due to the evolution of effective communication networks within and between the classes and improved mobility. Communities became more dispersed and not as close-knit as they used to be. In this environment signals of wealth and position are displayed more effectively through lavish expenditure on consumption and services, not leisure activities (Trigg 2001). Though conceptualized to explain the behavior of the leisure class in response to the increasing wealth of the working class in the late 1800s in the USA, it is also argued that conspicuous consumption behavior can be observed across all social classes (Veblen 1899), and it has an influence on sustainable development. Indeed, in recent decades policymakers have turned their attention toward promoting sustainable consumption. Sustainable consumption is defined as the consumption of goods and services that are produced in an economic manner using techniques and materials that do minimal damage to the environment, are socially equitable, and meet the basic needs of all humans.

Over the past few decades, policymakers have diverted attention to sustainable consumption, as a

means of achieving national sustainable development (Cohen 2005). The idea is that the promotion of sustainable consumption will address the environment costs and economic inequality associated with modern consumerist lifestyles. It is considered that when dealing with environmental issues, policymakers should not only focus their attention on the production side of industrial corporations but also need to encourage responsible consumption behavior from consumers. Consumption behaviors can have a social, economic, and environmental impact. In order to encourage responsible consumption behaviors, it is important to understand what drives consumption in the first place. Conspicuous consumption is one of the fundamental theories in explaining consumer behaviors. Conspicuous consumption is now examined.

Conspicuous Consumption and Emulative Consumption

Under the sociology of conspicuous consumption, social status can be signalled through luxury consumption. As a result, conspicuous consumption can be applied to explain emulative consumption among consumers. Emulative consumption suggests that most consumers consider their ideal consumption level as being in a level that is slightly higher than their affordability and emulate their consumption in accordance with those who have higher income. "The result is that the members of each (social) stratum accept as their ideal of decency the scheme of life in vogue in the next higher stratum, and bend their energies to live up to that ideal" (Veblen 1899, p. 84). The two concepts, conspicuous consumption and emulative consumption, frame consumer behaviors or consumption preferences as a tool used by individuals to establish or maintain their status in the social hierarchy.

Problems with the Concept of Conspicuous Consumption

From the outset, the concept of conspicuous consumption has received a lot of attention in the

consumer behavior literature. Its assumptions have been called into question. Conspicuous consumption assumes that taste can only "trickle down" from upper class to middle class and working class, and not vice versa (Bertrand and Morse 2016). The "trickle-down" model of tastes of consumption from upper class to middle class and working class is deemed to be too restrictive in modern society, as tastes of consumption can also be "trickle-round" (Trigg 2001). The "trickle-round" model implies that tastes are transmitted around in the social hierarchy, where consumers from the upper class, middle class, and working class influence each other. It has later been argued that there is also a "trickle-up" transmission of taste, from middle class and working class to upper class. Based on the original version of conspicuous consumption, two concepts are proposed in the literature to explain consumption behavior. These are called cultural capital and economic capital (Bourdieu 1984). Cultural capital captures consumption tastes and behavior that has been established over generations. For example, upper class individuals are more likely to have a taste for classical music and modern art. These are two examples of cultural capital that have developed over generations and are indicators of upper class social status. Many middle class individuals have generated "economic capital," a social status symbol that is derived from the accumulation of income. It is argued that the upper class, who have sufficient cultural capital, will strive to emulate middle class consumption in order to outflank them (Trigg 2001). Hence, the transmission of taste is not only "trickle-down" but also "trickle-up" and "trickle-round."

In addition, conspicuous consumption has been criticized as being out of date and limited, since social hierarchies that used to exist when it was first theorized in the late 1890s are less prominent today. In addition, it fails to capture post-modern lifestyles. The changes in consumer behaviors and lifestyles since the twentieth century have made the theory less relevant. As Mason (1998) explains, modern consumers pursue their social classes through adopting certain lifestyles and establishing personal images. The old way of displaying wealth through luxury goods

consumption is abandoned. Therefore, the theory of conspicuous consumption is out of date due to “the new cultural makeup of contemporary consumer society” (Trigg 2001, p. 104).

Nonetheless, there is also literature supporting Veblen’s theory. Christen and Morgan (2005) support Veblen’s theory and its application in modern consumers. They illustrate that conspicuous consumption can cause consumers to borrow money for consumption to “keep up with the Joneses.” Jaikumar and Sarin (2015) show that conspicuous consumption also exists in less developed areas due to the lack of attractiveness of alternative mechanisms to signal status as well as the lack of sufficient financial support locally to help prevent this kind of behavior.

Conspicuous Consumption and Bankruptcy

According to Veblen, consumers in each social class emulate the consumption behavior of the social class above them, and this kind of emulative behavior is one of the most important factors in determining consumer behavior. Consumers, through the purchase of goods that are slightly out of their affordability, achieve certain level of satisfaction in the identification of their social status in the society. Dwyer (2009) further develops this view and suggests that this kind of consumption behavior in modern society often evolves into a habit, a behavioral addiction that supports narcissistic behavior. As more people get addicted to purchasing goods for wealth identification, the emulative effect is diminished as the specific “luxury” goods purchased for the purpose of signalling social status become “standard” goods over time. In addition, consumers sometimes unconsciously consume conspicuously to maintain their standards of decency without trying to impress others (Trigg 2001). Consumer overindebtedness, and sometimes bankruptcy, can result from conspicuous and emulative consumption. As indicated by the theory of conspicuous consumption and its tendency to become a habit, consumers sometimes behave irrationally in consumption and can overspend on goods that are

beyond their affordability to display their wealth and for the pursuit of social status satisfaction. This kind of irrational consumption behavior tends to be persistent, and it results in consumers taking on debt than they can afford. Over time, the habit of conspicuous consumption increases the possibility of becoming overindebted or even bankrupt. This has a negative impact on a nation’s sustainable development. Overindebtedness can have negative impact on an individuals’ mental health and social status and also result in reduced income productivity.

Identifying and testing whether conspicuous consumption is associated with consumer overindebtedness is difficult as the main variables, conspicuous consumption and social status emulation, are hard to measure. Some studies on the impact of conspicuous consumption on consumer overindebtedness employ regional income distribution levels as proxies for measuring the potential for emulative behavior due to differences in social status inferred by differences in economic wealth (see, e.g., Christen and Morgan 2005; Zhu 2011; Georgarakos et al. 2014). The results of empirical studies suggest higher consumption by individuals leading to bankruptcy in regions where there is greater regional income variation indicating possible emulative consumption behavior (Adkisson and Saucedo 2012). Studies report that bankrupt individuals tend to spend at the same level as non-bankrupt individuals, and this occurs even when their respective incomes are lower (Zhu 2011). A reason forwarded by Zhu is that these individuals borrow more than they can afford, so they can consume in line with others who have higher income. Similarly, Georgarakos et al. (2014) find that conspicuous consumption has a significant influence on consumers’ debt levels. They report that the income level of a social circle is a significant indicator of the size of an individual’s loan. Specifically, the higher the perceived income of a social circle of individuals, the greater the risk that an individual with lower income levels will have higher debt levels and as a consequence experience financial difficulty. In these circumstances, the lower-earning individuals tend to borrow to emulate spending in line with their peers in the social circle. Consistent

Emulative Consumption and Bankruptcy, Fig. 1 Relationship between conspicuous consumption and bankruptcy

with these studies, Agarwal et al. (2016) illustrate that conspicuous consumption “serves as a mechanism for the relationship between keeping up with the Joneses and financial distress” (Agarwal et al. 2016, p. 3). Agarwal et al. (2016) found that consumers fund their emulative consumption using unaffordable debt when there are neighbors who have large lottery wins. Figure 1 illustrates the relationship between bankruptcy and conspicuous consumption behavior.

The motive of keeping up with those in a higher social hierarchy or displaying wealth within the current social hierarchy causes individuals to consume visible goods that are associated with the higher social status group. When the consumption is financed by unaffordable debt, then over time, an accumulation of debt results in overindebtedness, financial distress, and possibly bankruptcy.

While several studies have reported an association between emulative consumption and income equality, the results are not unanimous. Indeed, using USA state-level panel data from 1986 to 2003, Hwang and Lee (2017) find that there is a negative relationship between income inequality and the average level of conspicuous consumption. The explanation for their result is that the rich regard conspicuous consumption as “a strategic complement” to distinguish them from the poor. If income inequality is low, the rich are motivated to consume conspicuously to emphasize their higher status; however, the poor class is also motivated to consume conspicuously as it is easier for them to match the consumption of the rich who earn slightly more than them. If income inequality is high, the rich are less likely to consume conspicuously as their higher social status is more secure and the poor are less likely to try to emulate the rich as the gap is too great. Hence there is a decreased “marginal utility of conspicuous

consumption” in these circumstances. Hwang and Lee (2017) do not dispute the existence of conspicuous consumption by consumers; however, they argue that the relationship with income inequality is not straightforward.

Summary

In conclusion, conspicuous consumption has been a major theory in explaining consumer behaviors, and it has received both support and criticism from the literature. The fast-changing society as a whole means that people no longer acknowledge the old social hierarchy. Instead, different lifestyles are adopted, which focus more on individual choices and comfort. However, research identifies that emulative behavior still exists. Income inequality can trigger unsustainable consumption resulting in consumer overindebtedness. Studies have reported that some individuals consume more than they can afford to keep up with their peers. This, along with other factors, contributes to the increase in personal overindebtedness, which has a negative impact on a nation’s social and economic well-being. Policymakers are trying to promote sustainable consumption as a “new style” of consumption that they hope will substitute for the overconsumption of expensive luxury status goods. This should not only result in a better environmental footprint but should also reduce conspicuous consumption behavior.

Description

In the accounting perspective, an endowment fund is an account on the balance sheet on the moment of its foundation that represents the own capital of the not-for-profit organization. In the finance perspective, an endowment fund is a permanent source of capital dedicated to a specific mission. During its activity, this fund normally provides from a donor, increases, or decreases the value with more donations that could have restrictions (permanent fund must generally be held indefinitely to perpetuity) to be deductible for the donor.

Key Issues

The not-for-profit sector is essential to the society and governments to provide wide range of social and human services that they are unable to offer to specific citizens, such as elderly, babies and young in danger, alcohol, drugs and other chemical dependence, orphans, and special needs citizens. Indeed, the growth of this sector demands private donors and foundations, the media, and the society to financially support these organizations. But

the scrutiny and the accountability by nonprofit organizations (Calabrese 2011) require more public discussion and as Mansfield (1982, p. 61) defines “for what (purposes are the services intended), to whom (are the services delivered), when (are the services delivered), and by what means (are the services delivered).”

Knowing, that “accounting is the language of business” (Davidson et al. 1977, p. 1, Bloomfield 2008, p. 433) and among not-for-profit organizations, the funding accounting is a very important area of concern, the author agrees with Gross et al. (2005, p. 8) that claim, “donors and watchdog groups pay close attention to fundraising expense as a percentage of total expense.” Moreover, Hansmann (1990, p. 38) claims that “maintenance of an endowment is often viewed as an objective in its own right, rather than as simply a means to an end.”

It started, in the 1980s, in the USA, the promotion of the endowment model based on the portfolio managers of Yale University’s endowment fund and follow, in years 1990s, “Europe Countries with deregulation of capital markets” (Koedijk and Slager 2021, p. 19). Several researchers, such as Fabozzi and Koedijk (2021, p. 3) define endowment fund as “is characterized by a low allocation to traditional asset classes (equities, fixed income, and cash) and a high allocation to a large number of alternative investment classes (leveraged buyouts, venture capital, hedged funds, managed futures, private-market real estate, managed futures, natural resources/commodities, and infrastructure.” Also, Jacobs and Kobor (2021, p. 14) characterize as “pool of capital generally funded through donations for specific purposes, designed to support the present and future goals of nonprofit organization.”

Consequently, these organizations receive funds from the governments, public entities, corporations, and the society, because donors or other stakeholders provided financial resources and some of them define with specific elements (Keating and Frumkin 2003). Furthermore, Brown and Moore (2001, p. 570) present a schema of not-for-profit accounting framework based on the rule “to whom, for what.”

Consequently, the growth of the not-for-profit sector demands more accountability, ethics, evaluation, and governance practices that have, also, implications in not-for-profit management education (Bies and Blackwood 2008).

Some critics have been made to the endowment model, for example, Siegel (2008) argues that the organization survival can be threatened, if the endowment fund is also indebted or contains implied debt because of contractual capital calls that have been promised to managers but not yet delivered. Also, Siegel (2021) involves long-run prospects for the endowment model are favorable, because the model relaxes on many constraints that keep other types of investors from achieving maximal risk-adjusted return.

This increases the responsibility with disclosure of the annual report of the not-for-profit organizations that developed at local, regional, national, and international activities, and then they must provide accounting information system, specialized on not-for-profit organization, where donations and endowment funds are reported and explained.

Key Financial Issues

Since the financial vulnerability of the not-for-profit organization demands more needs of knowledge and understanding of other options to reduce these vulnerabilities (Tevel et al. 2015), Dryburg (2017, p. 1) presents definitions of endowment fund related with its role as stakeholder on the not-for-profit organization, such as the following:

To a donor, an endowment is a sum of money given to a charity for charitable purposes, with only the “income” being spent and “principal” being preserved; To an accountant, it is a fund which is “permanently restricted”; To a lawyer, it is an institutional fund not wholly expendable on a current basis under the terms of the gift instrument; To the not-for-profit organization board, the restricted endowment or “quasi-endowment” is created when the donor defines unrestricted funds or imposes a spending restriction; To the

investment management industry, it has a propensity for fund mergers, profit-sharing agreements, and other collaborative arrangements.

The author agrees with Hager (2001) when claims that more managers know about how accounting decisions affect their organization, more they can do to adopt strategic approaches to keep their organizations afloat. So, this raises from the practical contribution of boards that publish accounting standards or rules where this endowment fund is discussed.

Key Accounting Issues

In or after April of 1983, the International Accounting Standards Committee issued the International Accounting Standard (IAS) 20 – *Accounting for Government Grants and Disclosure of Government Assistance*, and, in April 2001, the International Accounting Standards Board (IASB) was issued that specify conditions to receive assistance may not be specifically related to the operating activities of the organizations (IFRS Foundation 2014, p. 1). Also, the disclosure of government grants must follow IAS (20.39) which is the following:

accounting policy adopted for grants, including method of balance sheet presentation nature and extent of grants recognised in the financial statements; the nature and extent of government grants recognised in the financial statements and an indication of other forms of government assistance from which the entity has directly benefited; and unfulfilled conditions and other contingencies attaching to government assistance that has been recognised attaching to recognised grants. (IFRS Foundation 2021, p. 10)

After June of 1999, the Financial Accounting Standards Board (FASB) issued the Financial Accounting Standard (FAS) 136 - *Transfers of Assets to a Not-for-Profit Organization or Charitable Trust that Raises or Holds Contributions for Others* provides guidance for funding accounting where an “, the return on investment of those assets, or both to not-for-profit organization—the beneficiary—that is specified by the donor a transfers assets (FASB 2021, p. 1). It is important

to specify that the FASB Statement no. 116 – *Accounting for Contributions Received and Contributions Made*, in paragraph 4 refers: “does not apply to transfers of assets in which the reporting entity acts as an agent, trustee, or intermediary, rather than as a donor or donee” (FASB 2021, p.1).

The Financial Accounting Foundation (FAF) published, in 2014, the Standard 958-Not-for-Profit Entities (NFP) that report the financial statements of NFP that must fulfill the US Generally Accepted Accounting Principles (US-GAAP). Indeed, this standard, on paragraph 45.14, details “when classifying an endowment fund, each source-original gift, gains and losses, and interest and dividends-must be evaluated separately” (FASB 2014, p.14). In addition, the paragraph 45.15 provides guidance about the net assets of an endowment fund in a statement of financial position, such as the following:

Permanently restricted net assets. For example, the portion of a permanent endowment that must be maintained permanently-not used up, expended, or otherwise exhausted-is classified as permanently restricted net assets; Temporarily restricted net assets. For example, the portion of a term endowment that must be maintained for a specified term is classified as temporarily restricted net assets; Unrestricted net assets. For example, a board-designated endowment, which results from an internal designation on unrestricted net assets, is not donor restricted and is classified as unrestricted net assets. (FASB 2014, p. 4)

Furthermore, Topic 958 clarifying the scope and the accounting guidance for contributions received and contributions made (FASB 2018, p. 8) stipulate restrictions of the donor “(donors include other types of contributors, including makers of certain grants) that specifies a use for a contributed asset that is more specific than broad limits resulting from the following: The nature of the NFP; The environment in which it operates; The purposes specified in its articles of incorporation or bylaws or comparable documents for an unincorporated association.”

A relevant condition is made on the FAS update of the not-for-profit entities (topic 958), where it is defined that “laws may extend those

limits to investment returns from those resources and to other enhancements (diminishments) of those resources. Thus, those laws extend donor-imposed restrictions” (FASB 2018, p. 8).

The Governmental Accounting Standards Board publish the Statement of the Governmental Accounting Standards Series no 54 with title Fund Balance Reporting and Governmental Fund Type Definitions focusing on funding commitments and other commitments; on paragraph 69 – Committed fund balance – Management’s Discussion and Analysis for State and Local Governments, including states, cities, towns, villages, and special-purpose governments (school and public utilities), defines that special revenue funds are “resources that are legally limited to a particular purpose by a government that cannot be used for any other purpose unless the government removes or changes the limitation by taking the same action it employed to impose the limitation or by taking a higher authority action” (GASB 2021, p. 33). And GASB (2021, p. 33) details that it has been eliminating the word “legally because it implies a restriction that is enforceable by law and may overstate the strength of the constraints that can be imposed by a government upon itself.” The Governmental entities should report information about these funds.

The Uniform Prudent Management of Institutional Funds Act (UPMIFA) is a law adopted in the USA that offers guidance to charitable organizations concerning the management of endowment funds held by NFP, and it allows to categorize a part of a donor-restricted endowment fund of perpetual duration as permanently restricted net assets. Also, the UPMIFA (NCCULS 2006, p. 218) defines on paragraph 4702 that endowment fund means an “institutional fund or part thereof that, under the terms of a gift instrument, is not wholly expendable by the institution on a current basis. The term does not include assets that an institution designates as an endowment fund for its own use.”

After January of 2015, in Portugal, the Order n° 262/2015-XIX of the Secretary of State for Tax Matters, of July 16, 2015 (MFSG 2015), approved

Accounting and Financial Reporting Standard for Not-For-Profit Entities (NFPE), approved by the Decree-Law n° 158/2009 (MFAP 2009), changed for Decree-Law n° 98/2015, 2 of June (MF 2015). This standard aims to establish the main aspects of recognition and measurement, with the adaptations inherent to this NFPE. Thus, this standard, on the section 3.5 (MF 2015: 20863), details that:

the endowment fund constitutes the residual interest of NFPE in assets after deducting liabilities. The endowment fund can include certain categories of items whose use may be restricted. At NFPE, the endowment fund comprises funds of those awarded by the founders of the entity or third parties, by the funds accumulated and other surpluses, as well as by subsidies, donations and legacies that the government or other regulation body or the legal norm applicable to each entity establish that they are to be incorporated in it.

Summary

The endowment fund has increased the scrutiny from the society, media, state regulators, and governments due to the public information and because of scandals (Vermeer et al. 2014), and even there are literature that focus in the aggressive accounting behavior in not-for-profit hospitals (Krishman and Yetman 2011).

The endowment fund could be detailed for different types, such as expendable endowment, restricted permanent endowment, and unrestricted permanent endowment, knowing that several authors (Flynn et al. 2000; Granof 2001) argue conflicts of interest, changes in the entity’s strategy (values, mission, vision, values), or restrictions in circumstances of management (Kearns 1994); the reputation of the donor and honor to pay it may restrict the endowment funds (Rossouw 2006).

Synonyms

[Biocombustibles](#); [Bioenergy fuels](#); [Bioenergy sources](#); [Energy bioliquids](#); [Energy biomass fuels](#)

Definition

Energy biofuels refer to fuels obtained indirectly, through physical, biological, and chemical processes, from biomass, which can be used also to supply internal combustion engines. Biomass is considered a renewable resource and therefore

also energy biofuels can be theoretically available without limits.

Traditionally, the use of biofuels was linked to the transport sector, i.e., for the transport activities as substitute of fossil fuels. In addition to this classical use, however, over the last few years there has been a rapid expansion of the biofuel application fields towards electricity and thermal generation and, particularly, towards cogeneration. In the current definition of biofuels, therefore, the link with the transport sector has been overcome and greater emphasis is placed on the heterogeneity of the applications, allowed by the spread of endothermic engines.

State of the Art

Energy biofuel production has increased globally in recent years, thanks to the support and incentives adopted by the various promoter countries. First- and second-generation biofuels are today the possible alternative for reducing the environmental impact and the security of energy supply, as well as an opportunity for job creation and rural development. However, a series of doubts have recently been raised about the alleged negative impacts due to the production of biofuels and to their real sustainability. Global targets on the production of biofuels will have a strong impact on land use and agricultural product prices. Uncertainties were also noted on the performance in terms of reduction of GHG emissions of biofuels compared to fossil fuels, especially when the change in land use is considered (Tyner and Taheripour 2008; Finco and Padella 2012; Khanna and Zilberman 2017).

Types of Energy Biofuels

Based on the state of production techniques maturity and use, but above all the origin of the raw material used to produce them, biofuels stand out and are classified into three categories: first, second, and third generation (Fig. 1).

The first-generation biofuel category includes biodiesel, pure vegetable oils, bioethanol

Energy Biofuels,

Fig. 1 Classification of energy biofuels based on the origin of the raw materials used in the production process. (Source: Personal elaboration)

E

produced from cereals and sugary raw materials, bio-ETBE (Ethyl Ter Butyl Ether produced from bioethanol), and biogas; their production and applications are already underway, while the main margins for improvement concern the reduction of production costs, the optimization of the energy balance, the increase in the energy yields of the engines, and the increase in the percentages of use in mixture with fossil fuels.

First-generation biofuels are produced, using conventional technologies, from sugars, starches, vegetable oil, or animal fats. Since these raw materials are also food resources, the “food versus fuel” debate is the main problem related to first-generation biofuels (Zhang et al. 2010; Graham-Rowe 2011). The production of first-generation biofuels is limited because it could have a negative effect on food availability and biodiversity (Koh and Ghazoul 2008).

Second-generation biofuels have been developed in order to cope with the growing demand for biofuels (Carriquiry et al. 2011). They are produced from nonedible crops or portions of edible plants that cannot be used as food and are therefore discarded, i.e., stems, shells, wood shavings, and skins.

The second-generation biofuel category includes bioethanol produced from ligno-

cellulosic raw materials, biohydrogen, syngas, bio-oil, biomethanol, biodimethylether, bio-MTBE, biobutanol, and synthetic diesel; their production has started on an industrial scale but it includes still many experimental plants. According to experts, second-generation biofuels make it possible to reduce greenhouse gas emissions more than the first-generation ones. The production of second-generation biofuels, however, is more complex, since it is necessary to extract the useful raw materials from woody or fibrous biomass (Naik et al. 2010; Sims et al. 2010).

Finally, third-generation biofuels are instead produced from algae, especially micro-algae (Shuba and Kifle 2018). The production of “oilgae,” or fuel derived from algae, involves the fermentation of carbohydrates present in algae (Demirbas 2011; Alam et al. 2015).

Second- and third-generation biofuels are also called “advanced biofuels.” An example of advanced biofuel still under development is the renewable diesel derived from hydrogenation (hydrogenation-derived renewable diesel – HDRD). HDRD is produced from animal fats or vegetable oils that are refined in oil refineries. This biofuel can be easily mixed with oil.

Carbon Neutrality and Energy Biofuel Policies

Biofuels have been considered over time good alternatives to fossil fuels because they would allow the achievement of carbon neutrality. In fact, biomass, during the combustion phase, releases carbon dioxide, which is readily reabsorbed by the plants, which are the source of the biomass. Through this closed cycle, the plants remove the carbon from the atmosphere through the chlorophyll photosynthesis, releasing it again when they are burned. In this perspective, biomass would represent theoretically a zero-impact raw material, since the carbon footprint of CO₂ emissions would be zero and would not affect the final carbon concentration in the biosphere (Muench and Guenther 2013).

The decision to carry out a turnover and to introduce advanced biofuels was driven by the increasing over time awareness that using edible raw materials to produce biofuels is not always sustainable. While on the one hand the first-generation biofuels register some environmental benefits in terms of potential net carbon footprint, even if debated (Sedjo 2011; Muench and Guenther 2013), on the other hand they contributed over time to the intensive cultivation of sugar cane, rapeseed oil, or corn, reserved exclusively to the fuel industry, thus removing land from food crops. In fact, apart from food security issues, first-generation biofuels are closely related to landgrabbing, deforestation, and the damaging effects of land change (iLUC - indirect Land Use Change) (Havlik et al. 2011).

The potential advantages of energy biofuels can be their biodegradability, the reduction of greenhouse gas emissions, the reduction of ozone levels in the lower layers of the atmosphere, and the reduction of VOC emissions (volatile organic compounds). But these advantages combined with the environmental disadvantages of deforestation and intensive agriculture, deriving from the use of herbicides, fertilizers, and pesticides, and added to water consumption for crop irrigation and transport (Miglietta et al. 2018), providing a final balance which is not always

convenient in a sustainability perspective. In fact, other factors need to be considered in assessing the environmental impacts, footprints, and sustainability of biofuels, e.g., emissions for the production and transport of biomass, irrigation and use of fertilizers, and emissions for the production and transport of biofuel. Thus, considering the entire life cycle management, from biomass production to distribution, not all biofuels can be considered carbon neutral or overall environmentally sustainable (Johnson 2009; Muench and Guenther 2013).

Summary

Energy biofuels refer to fuels obtained indirectly, through physical, biological, and chemical processes, from biomass, which can be used also to supply internal combustion engines. Biomass is considered a renewable resource and therefore also energy biofuels can be theoretically available without limits. Energy biofuels represent today the possible alternative for reducing the environmental impact and the security of energy supply, as well as an opportunity for job creation and rural development. Based on the state of production techniques maturity and use, but above all the origin of the raw material used to produce them, biofuels stand out and are classified into three categories: first, second, and third generation. First-generation biofuels are produced, using conventional technologies, from raw materials which are also food resources. Second-generation biofuels have been developed in order to cope with the growing demand for biofuels and to avoid the “food versus fuel” competition. They are produced from nonedible crops or portions of edible plants that cannot be used as food and are therefore discarded. Finally, third-generation biofuels are instead produced from algae, especially micro-algae. Considering the entire life cycle management, from biomass production to distribution, not all biofuels can be considered carbon neutral or overall environmentally sustainable.

Energy Conservation: More Efficient Use of Energy

[Consumption of energy](#); [Energy efficiency](#); [Energy management](#); [Energy saving](#)

Definition

Today, reaching energy is the most natural human requirement. Reliable, cheap, and clean energy supply has become the most important problem of recently for economic, social development, and humane living. It is known that 1.3 billion people in the world do not have the opportunity to benefit from energy. Unfortunately, energy resources are among the most important causes of war in the world.

The concept of energy saving is of vital importance in every daily field. Saving means “doing

the same job using less energy.” Conserving energy does mean not to the use of energy (Banerjee, 2015). It means using energy more efficiently by using known general methods, development procedures, and new technologies, and taking into account the standards of social life. It includes measures precautions to identify unnecessary usage areas of energy and to minimize or eliminate waste. In this way, the manufacturer can increase the competitiveness in the national and international area by producing the same amount of goods or services with less energy (URED, 2013).

There are two main ways of minimizing the carbon emissions caused by the burning of fossil fuels and preventing global warming produced by these emissions and the climate changes that occur accordingly: (1) using renewable and environmentally friendly energy sources instead of fossil fuels and (2) saving energy by using energy more efficiently. As can be appeared, saving in energy plays an important role in reducing carbon emissions.

Energy conservation is not using energy or using it limitedly, and it is using energy efficiently. Energy efficiency is the reduction of energy consumption per unit of service or product quantity without causing a decrease in the standard of living and service quality in buildings and production quality and quantity in industrial enterprises (Levine & Kendall, 2007). It is possible to contribute to the individual budget, the country’s economy, and the protection of the environment, without restricting the needs, by using energy efficiently in every phase of daily life while meeting the heating, lighting, and transportation needs, using electrical household appliances (Sait & Hussain, 2015; Wang & Moriarty, 2017).

Many institutions around the world encourage sustainable growth and private sector initiatives by investing in energy-efficiency projects. Organizations such as the World Bank, European Union, United Nations, International Finance Corporation are leaded. The aforementioned organizations continue their support by pioneering investments in energy efficiency, especially through several economic instruments such as

incentives and grants. However, many institutions at local or national scale continue to work in the field of energy efficiency. Universities, private sector, nongovernmental organizations, foundations, and associations come to the fore in this field. Moreover, governments and public institutions are working overtime to spread national awareness of energy efficiency. The main objectives of all these institutions and organizations in energy can be summarized as reachable of affordable, reliable, sustainable, and modern energy to everyone. Furthermore, efficient use of energy in production and consumption processes is accepted as a common denominator.

Energy Conservation in the World

Population growth, globalization, rapid development in technology, a rise in income, and welfare have led to an increase in energy consumption since the mid-1900s in the world, and “fossil fuels” have been seen as the easiest way to meet this increasing demand. However, when the factors (limited resources, the oil crisis, increases in energy prices and its effects on the world economy, environmental pollution, climate change, etc.) are evaluated together, there is no solution other than turning to energy efficiency and renewable resources to get rid of this impasse.

Nowadays, energy efficiency has become a trend as the high amount of energy consumption naturally pushes countries towards efficient use of energy. Therefore, some countries lead in terms of energy saving. Especially, it is remarkable that developed countries are at the top of the list (Table 1).

One of the important indicators in energy efficiency is energy density. Energy density is a globally used indicator representing the amount of primary energy consumed per gross domestic product (GDP), and it gives an idea about the path taken in energy efficiency applications. The ideal condition for a country’s energy development is high per capita energy consumption and low energy intensity. The global energy density is shown in Fig. 1 (EIA, 2018).

Energy Conservation: More Efficient Use of Energy, Table 1 The ranking of leading countries in energy consumption (ACEEE, 2018)

Sort order	Country	Country score	Sort order	Country	Country score

11	ABD	55,5	24	BAE	18
12	Mexican	54	25	Saudi Arabia	16,5
13	South Korean	52,5			

Energy Conservation: More Efficient Use of Energy, Fig. 1 Global energy density (1.000 BTU/\$ 2010 GSYIH*, 1990–2017) *Refers to 1,000 British Thermal

Units (British Thermal Units, BTUs) energy spent to produce 1 unit of GDP. Also, GDP is arranged according to purchasing power parity

However, using the GDP calculated for a country by converting it with a common exchange rate for comparison between countries does not give correct results due to differences in development/price level between countries (WEC, 2010). Therefore, purchasing power parity (PPP) has been developed to eliminate the price differences between countries and to compare real goods and services volumes. It is seen that using PPP instead of exchange rate in the calculation of energy density gives better results in comparison between countries/regions with different economic development levels.

The importance of energy efficiency is perceived differently by countries and different measures/solutions are applied. The precautions taken by countries on energy efficiency are shown in Fig. 2 (WEC, 2010).

However, experiences by this time show that the most important issue is that the state regulates (minimum energy efficiency (performance) standards, labeling, mandatory audits, having an energy manager, reporting consumption) as well as supporting energy efficiency practices in economic and financial matters (with incentives, tax relief, low-interest loans) and it leads (Martinez et al., 2019).

Energy Conservation: More Efficient Use of Energy, Fig. 2 Precautions taken for energy efficiency in the world

Energy Conversation in ABD

The USA was one of the countries that first realized the importance of the energy efficiency issue and has been on this subject with an increasing momentum since the 1970s. While an annual decrease of 0.5% was achieved in energy density from 1949 to 1973, an annual decrease of 2.7% between 1973 and 1980 and an annual decrease of 1.6% in the period 1980–2004 was achieved (U. S. EERE, 2014). As a result of these studies, in 2005, a savings of 70 quadrillion Btu (1.8 billion TEP) was provided, corresponding to \$ 700 billion in energy consumption (Rosenfeld, 2007).

As a result of the energy efficiency studies carried out in the USA, the following gains have been succeeded between 1973 and 2005: (1) Energy efficiency has become the largest and domestic energy source. (2) An equivalent contribution has been made to the removal of 1 billion cars from the roads in environmental protection. (3) With the improvement of the efficiency of the

refrigerators, there was no need to install an additional power plant of 30,000 MW. (4) As a result of the insulation applied in the buildings, 250 billion dollars saving equivalent to 4 billion barrels of oil per year and 1340 million tons less CO₂ emission to the environment has been achieved. (5) Ninety-seven nuclear power plant projects with a capacity of 107,000 MW, which were planned to be built, were canceled for the growing energy needs of the growing economy (No new nuclear power plant has been established since 1978). (6) Energy conservation in federal government buildings increased by 20% over the period 1985–2000 (Çengel, 2013).

The USA did not consider the above success in energy efficiency sufficient and prepared a National Action Plan named “Vision 2025.” The Vision 2025 Plan is organized around the following 10 goals (EPA, 2008):

Considering economic energy efficiency as a priority resource

Taking precautions to encourage energy (production/distribution) companies to invest in energy efficiency instead of new energy investments

Development of economy tests

Development of measurement, evaluation, and verification mechanisms

Improving mechanisms for determining effective (useful) energy efficiency projects

Developing policies for healthy energy efficiency practices

Aligning consumer prices and incentives for energy efficiency investments

Establishing modern/detailed energy billing systems

Establishing modern systems to effectively share and deliver the latest information on energy consumption/efficiency with consumers

Incorporation of the latest technologies in applications (e.g., cogeneration)

Energy Conservation in EU

As in all over the world, EU countries have started to work to reduce oil dependency/increase supply security, reduce energy costs/support competition, reduce unemployment, and protect the environment/reduce greenhouse gases from the beginning of the 1970s, when the oil crisis was experienced, and they planned to reduce energy intensity and has achieved considerable success in this (EC, 2005).

Between 1996 and 2007, a savings of 160 million TEP was achieved in 2007 with a 13% increase in energy efficiency in end users. Fifty-two percentage of these savings come from industry and 32% from transportation (EC, 2009). The change in energy consumption and energy intensity in the EU-25 countries between 1990 and 2020 is observed.

In EU countries, it is aimed to achieve a 20% reduction in greenhouse gases until 2020, to reach 20% of renewable resources in energy consumption, to decrease 20% below 1990 consumption in energy consumption, but it has been determined

that the target will not be achieved in terms of energy consumption (calculated rate 9–10%) (EC, 2011).

To achieve this projected target, a new energy efficiency directive was prepared and introduced in June 2011, considering that more initiatives should be taken as a result of the studies. This directive is planned to be started at the end of 2012 after the necessary procedures have been completed and to be initiated at the end of 2013. The new energy efficiency directives can be listed as follows:

Leading the government sector in energy saving

Receiving energy services suitable for the needs of consumers for maximum benefit and providing information

Improving energy efficiency in energy production and distribution

Raising awareness of the benefits of energy efficiency improvement in the industry

When the energy strategies of the EU countries based on three fundamentals are considered consideration from the new energy efficiency directive, it is thought that the following benefits will be provided:

1. In the field of sustainability: CO₂ emission reduction, limitation of environmental damage
2. In the field of supply security: Decrease of EU's energy dependency, a decrease of energy infrastructure investments, change of trade balance in energy
3. In the field of competitiveness: Decrease of € 200 billion annually in EU's energy bill in 2020, creation of two million new jobs by 2020, acceleration of R&D and markets for the global leadership of the EU (EC, 2011)

Summary

Energy conservation: It can be defined in two different terms as obtaining the same product or service (without compromising quality and

comfort conditions) with less energy and obtaining more products or services with the same unit of energy. In general, energy saving has a wide scope such as environmental protection, world and country economy, unemployment, and individual budget. In other words, energy efficiency is seen in many areas from energy acquisition to transmission and distribution, from production in industry to heating-cooling-lighting in the residential and service sector, from household appliances and office devices to transportation. As a result of the increase in population and the development of technology, the energy need (demand) increases, and when the existing production (supply) is not sufficient to meet this demand, new investments are made to meet this need. However, it is possible to meet the energy deficit with energy efficiency, which can be called as free energy (megawatt, megajoule in terms of negative energy in some sources) with investments to be made primarily in energy efficiency.

It is seen that global developments within the scope of energy conservation are discussed in the context of sustainability. Investments made in this field are in a critical position in building the world of the future. On the other hand, if countries do not continue to focus on energy efficiency and develop new strategies in this regard, the momentum registered in this area in recent years will face the risk of slowing down. Another important issue that should be emphasized here is, there are serious differences between countries in energy efficiency. Therefore, the developments in the aforementioned area should be universalized to the base and spread all over the world. In this direction, it is necessary to focus on the energy issue by setting certain broad cooperation proposals and targets.

²Dokuz Eylül University, İzmir, Turkey

Synonyms

Demand-side management (DSM); Demand-side response; Load management

Definition

Energy can be supplied via many sources, from on-site generators to international interconnected power. However, energy consumption varies throughout days and seasons, and leads to peaks and valleys in the energy demand, when there is a maximum or a minimum demand. Stabilizing the relationship between demand and supply is a complex challenge; while traditional energy management approaches look for ways to match supply with demand, energy demand management, i.e., demand-side management (DSM), approach reverses the problem. It encompasses the management of energy after the meter and includes all the measures that can be taken by the consumer and actions of demand decrease, demand response, and market strategies form the basis of energy demand management. In a broader definition, energy policies for energy security, affordability, and emission (or carbon) management are emphasized. The actors of demand management are consumers, utility companies, network operators, and governing institutions. The consumers are

engaged and encouraged to change their energy use patterns through making conscious choices by knowing about amount and cost of their energy consumption. While governing institutions regulate energy demand management measures, regulations are implemented by the utility companies and network operators. Utility companies offer an increasing number of options for demand management and educate the public about them. Regulatory support, financial incentives, and new technologies are limiting issues for the implementation of energy demand management.

The Role of Energy Demand Management

Most of the consumed energy in the world is powered through the electricity distribution grid. There is a continuing increase in the global demand for energy even though some systems such as transportation and structures under extreme conditions are apart from the grid. The traditional energy management approach is matching increasing energy demand by increasing energy supply, which has been largely successful when the most common energy service was electricity generation from fossil fuel resources. Its success is mainly because generating electricity from fossil fuel resources is a very flexible system. In this context, the way to deal with increasing loads is to increase the capacity of power plants and building reserves for peak loads and losses in the system. The capacity for peak load is rarely used, therefore interconnecting with other countries or power stations and forming a wide network is a possibility, yet when a network becomes big, there is more chance that a glitch in one area will cause instability in other areas. In addition, 10–50% of electricity is lost during transmission and distribution in addition to losses related to conversion inefficiencies during its generation. Moreover, electricity generation has an impact on various environmental systems.

Since energy plays a more dominant role in peoples' lives, many countries are dependent on oil and gas imports from certain regions of the

world for providing energy resources like oil and natural gas, thus energy independence and energy security are important goals in the political agenda of these countries. The energy crises and growing environmental concerns have made it necessary to search for alternative and low carbon energy resources. This is also a reason to invest in and encourage more diverse and decentralized energy resources. Lowering carbon emissions from energy production is a concern in building new capacity. Each energy source has its advantages and disadvantages. Nuclear power is inflexible due to some technical and economic issues (Verbruggen 2008). Wind power is a mature and feasible technology and solar power is becoming more feasible yet their intermittent nature causes problems. Other technologies like hydrogen and wave power are expensive and require more research before implementation. Building new capacity and betterment of the traditional grid are still valid options; however the centralized structure of the traditional grid is not very suitable for integrating new power sources from renewables. The utilization of renewables would lead to decentralization and require new policy and regulatory solutions.

Energy demand management, i.e., DSM looks for ways to match demand to supply by pulling the consumer into the sector as a stakeholder. Evans et al. (2012) report that the term demand-side management (DSM) was first used in 1984 by Clark Gellings as “DSM activities are those of which involve actions on the demand (i.e., consumer) side of the electric meter, either directly or indirectly stimulated by the utility”. A limited definition of DSM only concentrates on electricity load, where the main instruments of DSM are demand decrease, demand response, and market strategies. Gellings (1985) also relates to planning, implementation, and monitoring of utility activities. In addition to activities, DSM establishes a dialogue between the suppliers and consumers for mutual benefits (Babu et al. 2008). Active collaboration becomes possible with the flow of energy and data in two directions (Costanzo et al. 2012). Hence, a broader scope includes nonelectric measures and loads such as thermal and transportation energy requirements. DSM strategies balance demand

Energy Demand Management, Fig. 1 Main strategies of DSM

and supply, in other words the needs of consumers and utilities mainly by educating, influencing, and changing energy use profiles of consumers. Main strategies of DSM are twofold; one side aims to manage the loads and increase management performance by demand decrease, load shift, and load response, while the other side emphasizes demand participation from the consumers and market with energy management, security, and affordability as main issues (Fig. 1).

Demand Decrease Strategies

From the consumer’s point of view, decreasing energy demand starts with “energy efficiency” and “energy conservation.” They can be sometimes used interchangeably; however, energy efficiency deals with decreasing the amount of energy for a service while energy conservation concentrates on decreasing the yearly total amount of energy consumption. In the context of DSM, energy efficiency is used as a permanent reduction in energy consumption. Since efficiency is a relative term, comparing the energy consumption of options requires the use of an index related to the amount of energy, costs, carbon, etc. Consumers and energy managers are the actors that decide, make the necessary investments, and continue to implement energy efficiency and conservation strategies.

From the utilities point of view, DSM is necessary to reach a desired load shape. Even if it is for a short period of time, the maximum demand plus a safety factor and reserve capacity (of around 20%) determines the necessity for the energy production and transmission infrastructure. Therefore, the most problematic area of this shape is caused by the peak demand, and instead of building extra capacity, utilizing strategies for “peak clipping” protects the grid. “Islanding” can also decrease the grid’s complexity, so that a large system can be formed of smaller pieces that can be connected to and easily isolated or detached from the system to shed the peak load. The utilities can make citizens aware of cost-effective ways to reduce energy consumption through education and financial incentives (Energy Research Group 1986).

Demand Response Strategies

Consumers can use non-intrusive elements to monitor, control, communicate, and self-heal. For instance “smart meters” can be connected to all appliances and the consumers can use them to save electricity via monitoring their energy consumption on their tablets, smartphones, etc., while the utilities can turn on devices like washing machines when there is minimum cost according to tariff or maximum production for renewables. The smart meters use machine learning and deep learning methods and can learn from usage data. They can also be programmed according to a variety of criteria including seasonality, usage duration, appliance consumption, consumption price (type of day, daily time bracket, etc.). Thus they can typically decrease energy consumption by 9–20%. The issues of cost, privacy, and accuracy create a resistance to using smart meters (Krishnamurti et al. 2012).

Utilities use the strategies of valley filling, load shifting, strategic conservation, strategic load growth, and flexible load shape to manage the shape of the electricity loads (Malik 2001). “Energy storage” system can be a part of the energy infrastructure in a variety of ways. It can be used to store the produced energy before going

to the system or can be placed between the system and the utilization of energy. It is mostly used for load management by arbitrage, which is storing energy at low demand or low-price times and feeding the system or services at peak times. Distributed electricity energy storage can enhance the efficiency of renewables and the grid, and reduce degradation time of grid elements, which also helps with decreasing upgrade costs of the infrastructure. Since high capacity electricity storage technologies can be expensive and most of the technologies are still at research stage, using distributed small-scale energy storage for demand can usually be more beneficial.

Energy resources and infrastructure can limit or empower the response strategies. Carbon reduction goals put political pressure on building more low carbon resources such as distributed or sustainable sources. Solar and wind power are of special interest since they are feasible and can be applied in nearly any location. Since the amount of energy generated from such resources shows high variance and uncertainty, such systems require increased frequency response and flexibility. Therefore, flexibility that demand management offers is more valuable in such systems. High electricity load on the network also necessitates flexibility by demand response. Good, Ellis, and Mancarella (2017) put increased efficiency in grid and efficiency investment and operation efficiency as the recognized benefits of demand management for applications with high ratios of renewable/decentralized energy. Yet, these systems have higher complexity, which carry more risk for failure.

Uncertainties in the supply of these resources require “dynamic management.” Some smartness in the system can help with integrating the actions of users connected to the grid. Management of some controller parameters is necessary to make the system more stable, however their measurement process and communication causes some delays, which can degrade a system’s performance. The delay times differ in wired or wireless power systems. The total measurement and communication delay can be in the order of 0.5–1 seconds. This time delay can cause instability in variables of voltage, current, angle, and

frequency. Real-time optimization would ensure robust control and help to improve performance and stability. Tariffs can also be generated to respond to high demand amounts or times.

Market Strategies

The energy sector is rapidly changing with new goals every year. Decarbonization goal of Paris agreement is a prequel, and more stringent goals will be set in the future. Such goals can only be reached by engaging both the utilities and consumers, in which DSM concentrates on. Warren (2014) reviews DSM policies under the headings of regulatory, financial, market based, and voluntary. One policy example is the Revised Energy Efficiency Directive of the European Union (2019), which gives responsibility to utilities “to help their consumers use 1.5% less energy each year.” Yet Apajalathi et al. (2015) argue that current European policies place conflicting demands on the utilities and create a complex organizational structure, which make it difficult to both comply with the regulations and make different business units work together efficiently to produce valuable service packages (Apajalahti et al. 2015). They also remark that the consumers can be skeptical about believing the energy company’s motives to save energy for their customers, which would lead to a decrease in revenues. Therefore, the consumers were not willing to invest in deep relations with the utility company, beyond basic energy efficiency advice.

One of the most discussed and implemented DSM market scheme is the utilization of demand response tariffs. The utilities start their analysis with accounting how much energy is consumed in which time periods. Time of use (TOU) tariffs aim to decrease peak load or stabilize the load in a long-time frame. Torriti (2012) investigated TOU tariffs by looking at data from 1446 smart meters. He found that the introduction of this tariff increased the average energy consumption by 13.69% while decreasing electricity bills by 2.21%. This 2-year study showed a marked

difference in load shape and peak hours, even between the 2 years of using the TOU tariff.

New business models can help to implement DSM measures more efficiently. For example, utilities and consumers to coinvest in renewable energy resources. Utility companies can help building new solar systems on roofs by unifying the owners of the houses, providing technical and managerial support, and incentivizing electricity bought from this renewable resource. In return customers will let their roofs to be utilized and buy local and decentralized electricity with a reduced fee. In this business model, consumers also become prosumers and a cooperation between prosumers, producers, and utilities (operators) arise. Public procurement mechanisms can also encourage new business models in some countries.

Energy use patterns mainly depend on socio-demographic variables. Abrahamse and Steg (2009) argue that changing the energy use patterns requires cognitive effort for the users, and psychological factors are the most significant during this process. Therefore changing through gaining environmental or energy consciousness is important, and either the government or the utility companies can educate or run campaigns. Another option is knowing about the amount and cost of their and their neighborhood’s energy consumption to benchmark their energy use against their peers in commercial and residential areas.

Summary

The annual consumption of electrical energy is continuously growing and is expected to increase. In addition to this increase in demand for electrical energy, system operators encounter various problems such as fluctuating consumption, inefficient operated generators for short periods due to peak load. Furthermore, consumption patterns of users change according to time in daily, monthly, and yearly cycles. Due to the aforementioned causes, demand sometimes falls well below the

average and at times it forces the network to perform at peak demand. In this situation, the peak demand occurs for a short time, and the power stations allocated to meet this demand remain idle at other times. Another problem experienced by many countries is mainly due to the sources used in energy production being imported from outside the country. Besides increasing the dependency on foreign countries, this situation causes the costs to be reflected on the user bills. Moreover, since the energy sector is one of the key sectors against climate change; new policies, especially regarding emissions reduction and balancing supply and demand is necessary. Due to the problems of today's network and possible future challenges, the structure and operation of the network need continuous improvement. In this context, DSM can be used to perform a particular job in many different ways that emphasize different requirements such as peak demand reduction, filling low demand times, strategic demand saving, strategic demand growth, load shifting, and flexible load shaping. Advanced intelligent load control within DSM aims to manage the loads and to increase the performance of management. From another point of view, the effectiveness of DSM measures is usually related to the importance given to DSM by policies. Decreasing energy consumption, responding to demand by managing the load and allocating available resources, and encouraging via policies and market tools are the main strategies of DSM. The monetary resources needed to ensure the widespread use of DSM approach can be obtained from the savings related to decreased plant installation and operation expenses, due to the decrease in the peak demand, and the gains from the electricity bills of the consumers. DSM requires both the consumers and utility companies to co-benefit from bettering the energy system and decreasing energy consumption. In addition to regulatory support, many financial incentives are provided; yet, trust between the consumers and the utilities has to be formed to decrease the amount of energy consumption and take mutually beneficial steps to better the network.

New technologies such as smart grid, smart meters, and energy storage systems are researched and implemented to make better use of the opportunities of DSM. In this context, smart cities can make more efficient use of resources. Renewable energy resources like wind, solar energy, and geothermal can be integrated into the energy systems via smart grids, this way sustainable energy resources can be a part of the smart city's automation. The local authorities can control the energy demand for transportation, lighting, and other necessary systems with the smart city concept. Energy policies need to consider the integration of all these systems and the connected smart grid. Spreading the demand in an intelligent way helps DSM. In the near future, DSM will be integrated into the energy sector in the planning phase. However, demand participation needs to be carefully planned for integration into the existing electricity market, because every new structure added to the system would bring new complexity and problems.

Definition

The built environment plays a very significant role in responding to climate change. Decarbonizing the building sector includes developing the design and procurement processes to improve energy performance and sustainability of buildings. Public procurement process has a key role in this development.

This chapter describes factors that should be taken into account when applying energy efficiency targets to public procurement process of buildings. The procurement process has been extended to also cover the life cycle of the building, to emphasize the connection between the decisions made during the actual procurement process, and the performance values affecting

the building's energy efficiency, indoor air quality, and life cycle economy.

Introduction and Background

The built environment sector has a vital role in responding to the climate change. While buildings are responsible for nearly 40% of global carbon emissions, decarbonizing the sector is among the most cost-effective ways to mitigate the effects of climate breakdown (WGBC, 2019). Energy demand from buildings and buildings construction continues to rise, driven by improved access to energy in developing countries, greater ownership and use of energy-consuming devices, and rapid growth in global buildings floor area (IEA, 2020).

The EU has set new rules for energy efficiency, including target of at least 32.5% by 2030 at Union level, following on from the existing 20% target by 2020. This means that primary energy consumption in the Union should be reduced by 26%, and final energy consumption should be reduced by 20% compared to the 2005 levels. The revised directive will encourage using energy more efficiently and aims at reduced energy consumption for households and businesses, lowering energy bills, and providing incentives for producers/manufacturers to use new technologies and innovate (EC, 2019; EC, 2018).

The EU legislation obligates the public sector of the Member States to procure energy-efficient buildings without compromising the indoor climate quality and to do so with the efficient use of public money. Buildings are a major part of public procurements. The value of public buildings in Finland is about 45 billion euro (ROTI, 2019). With major purchasing power, municipalities have the potential to provide significant leverage when seeking to steer the building market toward energy efficiency improvements (Vinokurov et al., 2019).

However, municipalities struggle with financing their investments, and the maintenance and renovation backlog of buildings is rising (ROTI, 2019). Furthermore, the evolution of municipalities as public utility is changing (Weidner et al.,

2011), and thus the purpose of the municipality-owned buildings is changing. By selling and leasing back a property to a private partner (Public-Private Partnership PPP), the public sector could at the same time outsource the needed financing, speed up the process of energy efficiency investments in their buildings, and release capital for other public investments. The private party profits from the lease-back fees through the contract phase.

In a municipal building procurement process, the municipal building department applies local, national, and international energy efficiency strategies and targets, combined with project-specific targets. The minimum energy performance requirements for building procurement projects are given in each EU member state's buildings code. In addition to these, also other aspects need to be taken into consideration, for example, the requirements concerning building's functionality, safety, economy, and cultural and ecological aspects. The building systems should be safe to use and have high energy efficiency with low life cycle costs (Vinokurov et al., 2019). The biggest barriers in the implementation of energy efficiency measures in buildings include resistance for new technologies, lack of knowledge, and high investment cost of the new technology (Darko et al., 2017). In this chapter, two latter are assessed.

Energy Efficiency in Municipal Building Procurement Process

Insufficient understanding of how to integrate energy efficiency into building procurement process remains to be one of the barriers hindering the development toward sustainable construction. Municipal building department officers need more skills and knowledge to appropriately define the requirements, qualify suppliers, and identify energy-efficient design options. Also, unclear responsibilities and inefficient communication between the municipal building department and the project partners can jeopardize successful implementation of a building procurement project (Vinokurov et al.).

In the following, an example of municipal building procurement process is introduced. This example is from a Finnish middle-sized city (approx. 75,000 inhabitants), there are variations in the process between other Finnish municipalities, towns, and cities. In general, the procurement process described here follows the common framework by the EU and the Finnish national procurement legislation.

The Municipal Building Procurement Process
The municipal building procurement process includes several stages (Fig. 1). Initially, proper targets have to be set for the project and the

building, in order to ensure that the building will serve its purpose efficiently and economically throughout its lifetime. In Fig. 1, the procurement process has been extended from the more traditional span of “from preliminary design to the end of construction” to consider also the utilization period and end of life of the building. This has been done to point out, that the decisions made even in the preliminary stages of the design process, have high impact on the building’s performance throughout its lifetime.

In the **preliminary design phase**, the general targets are described. Such targets are:

Energy Efficiency in Public Building Procurement,
Fig. 1 An example of municipal building procurement process.
(Adapted from: Vinokurov et al., 2019)

- What kind of activities and functions should the building support (e.g., primary school, office, domestic).
- What kind of economical restraints are there (e.g., €/m², € in total).
- What are the ecological requirements (e.g., carbon footprint, share of recoverable building materials, use of recycled materials).

The preliminary targets should also confirm that the proposed building project is necessary to meet the demand in its field of operation. If a school is planned to be built, it must happen only if there is a demand for that. For example, a new school can replace an old one that has been banned for use due to severe indoor air quality problems, or it can meet the demand set by increasing number of children needing education.

In the **concept design phase**, more technical requirements are set for the project, for example:

- Energy class for the building (e.g., A, A+, A++, nearly zero energy building, plus energy building).
- Indoor air quality (e.g., in Finland: Indoor Air Class S2/S1).
- Greenhouse gas emission requirements for the building (e.g., kgCO₂-eqv./(m² a)).
- Life cycle economy requirements (e.g., €/m², €/student, €/patient).

After setting the above mentioned, still somewhat higher level technical requirements, the selection of the concept for the building is carried out. The main designer should be selected at this point, and the targets already set should be at the core of the designer tendering process. This way the main designer has good directions during the whole design process.

At the end of the design process a winner concept should have been chosen, to be forwarded to a more detailed design. This selection process involves several concept proposals, from which the concept that meets, or even exceeds, the requirements is selected. The selection should be made as transparent as possible. This can be done simply by giving weights for different requirements (e.g., energy performance, life cycle

costs), and then calculating weighted points for all concept alternatives. The alternative that gets the highest weighted score is the winner.

After the concept has been selected, a **detailed design process** is carried out. At this stage the detailed building systems design is carried out, including heat distribution, cooling systems, ventilation systems, pumps, fans, heat exchangers, electrical systems, water systems, sewage systems, etc.

In the design process, an architect is usually the main designer. In addition to this, several other designers are needed in the design of building systems, from the fields of:

- Electrical uses.
- Ventilation and air conditioning.
- Heating/cooling systems.
- Lighting systems.
- Building automation systems.
- Domestic water systems.
- Sewage systems.
- Communication systems.
- Alarm systems.
- Access control systems, etc.

In order to make sure that the coordination between all involved design parties is effective, it is natural that the responsibility for all design work is given to the main designer. The main designer then organizes adequate communication between the parties so that the requirements for the design can be met during the process. The final design is then approved by the client, in many cases the municipal building department.

After the detailed design, the **construction phase** can begin. The subcontractors are tendered, and the selected subcontractors will carry out the plan. It is likely that during the construction phase the subcontractors suggest changes to the plan. These changes may be, for example, material changes or device changes. These suggestions have to be approved by the designer, and the impacts on the building performance and costs have to be acknowledged at this point.

At the end of the construction phase the building is approved by the customer, and the **utilization phase** starts. At the beginning, there is a

warranty period, usually 2 years for the building project as a whole. During this time, the customer can claim improvements. Furthermore, there usually are longer warranty periods for different building systems and devices.

The utilization phase of buildings is typically several decades, for example, 50 years. Hence, the performance values of the building determine a significant part of the overall impacts of the building. The following questions follow the procured building through its lifetime:

- Does it serve its purposes, does it have high utilization rate?
- Is it energy efficient in its operation, does it utilize renewable energy?
- Is it a healthy and safe working/living environment for the occupants?
- Does it support the environmental targets set for the region?
- Is it economically feasible?

During its lifetime, a building can be “updated/ upgraded” by renovating it, or parts of it. Many technical systems and devices have much shorter technical lifetimes compared to the building frame and structures, hence they have to be replaced earlier. At these renovation points, also building performance can be upgraded to a better level, e.g., by replacing older technologies with novel and more efficient technologies.

At some point, the building reaches its “**end of life**” status. At this stage, rather some years before, the process starts from the beginning. First, there is a consideration of whether there is still a need for the services the building has offered. If the answer is yes, then it should be considered whether a renovation or demolition and new building construction project should be started.

The Factors Affecting Energy Use and the Environmental Impact

Climate change is the main driver behind the development of most technologies currently. The targets and requirements of carbon neutrality shape also buildings and building systems. Since buildings have long technical lifetimes, it is

important to be able to “predict” the future as much as possible already in the preliminary stages of the procurement process. In Fig. 2, the main factors of energy efficiency, energy economy, and environmental performance are presented in a building’s context.

Already in the concept design phase, it should be noted that there may be some risks in the future, concerning what kind of selections are made. In order to avoid these risks, which will likely increase utilization costs, if realized, they should be included in the design process. For example, demand response options should be carefully considered when heating system is being selected. It is likely that there will be incentives for reducing peak loads in heating and electricity use, preparing for this will likely save costs during the long utilization period. Furthermore, the origin of consumed energy (heat/electricity) is significant: carbon neutrality means in practice using only renewable energy sources. Low energy consumption on all building systems is desirable, but not at the cost of decreasing the indoor air quality. On the contrary, increasing indoor climate quality, by for example increasing the ventilation rate, generally improves the comfort and productivity of occupants. In this context, increased energy consumption (higher ventilation rate results in more electricity consumption in the fans, more heating/ cooling demand, and also larger duct diameters may be needed to avoid noise from the system) should be compared against the upgrade effect of the service, i.e., indoor climate.

The Role of Indoor Climate Quality in Procurement

The indoor air quality (IAQ) has a significant impact on the comfort of the occupants. It has been shown (Allen et al., 2016; CABA, 2017) that there is a correlation between IAQ and productivity in office buildings: the more satisfactory the occupant feels the indoor environment is, the more he/she can concentrate on working. Also, there is a correlation between the decrease of IAQ and the increase of sick days in working environments (Milton et al., 2000). This translates more or less directly into extra costs. Hence, ensuring high standard IAQ leads likely to lower life cycle

Energy Efficiency in Public Building Procurement,

Fig. 2 The main factors of energy efficiency and environmental performance of a building. (Adapted from: Vinokurov et al., 2019)

costs, when the building is considered including also the service it provides, i.e., productive process.

Ensuring high-level indoor air climate also minimizes the risks of health hazards during the utilization phase. For example, maintaining a low underpressure inside (compared to the outside) prevents excess moisture to concentrate inside the wall structures. It also means that in cooler climates there should not be any air leaks from inside to outside, since as the warm indoor cools down, at some point the water vapor starts to condensate. This may happen inside the building

structures and cause moisture problems. This problem does not occur, when an air leak is from outside to inside, since warmer air can hold more water vapor than cold air. However, the pressure difference should be kept as neutral as possible, to avoid any high air leakages through the building envelope.

In Fig. 3, the main factors of IAQ management are shown. Most of the building systems have some kind of impact on the IAQ, therefore proper IAQ management requires smart automation systems with communication between technical systems via applicable interfaces. In public buildings,

Energy Efficiency in Public Building Procurement, Fig. 3 The main factors of Indoor Air Quality management. (Adapted from: Vinokurov et al., 2019)

the occupancy rates may vary greatly during a day, a week, or seasonally. The system has to be able to adapt to the changes so that energy efficiency and high-quality standard indoor climate are maintained all the time.

Life Cycle Economy of a Building

The most important decisions affecting the life cycle economy of a building are made during the design phases. Furthermore, the major part of the life cycle costs will be realized during the long utilization period. For these reasons, the design process should be thorough and carefully executed, considering all necessary aspects. Special emphasis should be put on energy issues as energy generation plays a major role in climate change. Also, energy costs cause generally a major part of a building’s life cycle costs.

The energy sector is transforming from fossil to renewable, this causes significant changes in the energy system infrastructure. The main trend is electrification, which means that also in buildings heating of spaces will increasingly happen utilizing electricity. In practice this means utilizing different heat pump solutions in heating.

In Nordic countries, district heating (DH) has been an efficient way to generate and distribute heat energy locally. The district heating systems typically involve one or several large base load combustion plants, and they can be heat-only generation plants or combined heat and power (CHP) plants. Both processes have high system efficiency and can be operated using renewable energy sources, i.e., biomass or biogas. In addition to the base load plants, there can be smaller middle load and/or peak/reserve load units to be used during the colder periods, when more heating energy is needed. The structure of the regional heating system is built so that energy and cost efficiency can be maintained at high level in the whole system. Typically, the peak load units use fossil fuels to generate heat. However, their annual operation period is short, typically hours or days annually.

The combustion of fuels always produces CO₂ emissions to the atmosphere. For biofuels, energy generation is usually considered carbon neutral. Currently it is seen that in order to reach the overall carbon neutrality, CO₂ should not be released from the combustion plants in the future.

Possible requirements for CO₂ capture from the flue gases may increase heating costs in buildings connected to such DH grids. However, also the DH grids are under transformation and will likely shift slowly from centralized combustion plants toward utilizing more heat pumps and heat storages, resulting in lower CO₂ emissions.

Renewable energy can be generated on site, usually this means at least utilizing local photovoltaic (solar) power plant or heat generation by solar collector. Depending on the utilizable area for solar power production and consumption patterns of the building, at least some share of the electricity (and heating/cooling, via heat pumps) can be produced to compensate the energy demand of the building. During high solar intensity periods, even more energy than building's demand can be produced on site. This excess energy can be sold to the local grid, if it is allowed by the local electricity company. This requires a two-way electrical connection to the grid. Excess electricity can also be stored locally in batteries, such as building battery storages or even in electric vehicle batteries. Building dedicated battery storages are available, but still expensive currently. The market for electric vehicles is developing, the major car manufacturers have started to offer also full electric car models, in addition to plug-in models and hybrids. Integrating energy generation, storage, and demand response functionalities into building automation system enables building to be operated as a virtual power plant (VPP) in energy markets. As a practical example, see for instance Siemens (2020). Such operation will provide additional incomes for building manager/owner, while contributing positively to energy system flexibility needs.

The more a building has the ability of shaping its electricity (and heat) consumption during peak demand periods, the more cost efficient it will likely be. The costs caused by having the capability to adjust the consumption (smart monitoring and automation systems, two-way connections, batteries, EV charging poles, etc.) have to be compared with the savings they can bring throughout the life cycle.

Financing the Procurement by PPP Process

One of the biggest barriers in procurement of energy-efficient buildings is the high investment costs of new technology (Darko et al., 2017). Municipalities have a lot of investment needs in a variety of sectors, building sector being only one of them. Public-Private Partnership could be adopted as a financing method for public procurement for instance in the construction phase of a new building. Furthermore, the major renovation process of an old building is often postponed because of lack of finance and could be sped up with Public-Private Partnership.

There are different ways to execute PPP process and to share the responsibilities among parties. Usually the private partner is responsible at least for designing, building, and operating the building. The responsibilities are all specified in the contract (Tieva & Junnonen, 2009). Hereby Public-Private Partnership can be viewed not only as a financing method but also as a way of risk management: the public community hands the responsibility of the building to the private party (Weidner et al., 2011). In addition to the responsibility hand off, there is a smaller risk for the public sector about the building management, because the service fee is only paid in the case the service private party offers corresponds to what is agreed (Junnonen & Tieva, 2009). Also, if the building and its services are no longer needed after agreed lease-back time, the private partner will deal with the risk, if there is no other statement in the contract. The other benefit of PPP process to the public sector is usually fast building time, because the private sector wants to get the building up and running as soon as possible to get its profits (Tieva & Junnonen, 2009).

PPP contracts are complex and they require careful planning and negotiation. Along with good planning and finding a suitable private partner for the process, the contract negotiation phase is extremely important since the identification of risks is essential for successful procurement. (Tieva & Junnonen, 2009). Li et al. (2005) suggest ways to share the risks by their type to either the private or public partner. They also state that public sector should be better able to create strategies for risk allocation.

When talking about the building life cycle, also the user of the building should be addressed. The Public-Private-People Partnership (4P) aims to do just that, to have the user in the procurement process as a third party, emphasizing the user's actual needs (Kuronen et al., 2010).

Responsibilities of the Public Procurement Process

Including energy efficiency in the procurement process means in practice increased level of energy, environmental, and responsibility issues be introduced and added to the more traditional procurement system. It is the customer's benefit, if the responsibilities in the public procurement process are clear and transparent. Vinokurov et al. (2019) have suggested the following clarifications to be included in the procurement process for ensuring a good energy efficiency, indoor climate, and life cycle economy:

- *The building department steers the project, sets the energy efficiency targets for the project, and ensures that all project partners have sufficient and timely information, and resources to carry out the project successfully. Among the building department's responsibilities are:*
 - *Selection of the optimal concept design from the proposals of designers.*
 - *Approval of detailed designs.*
 - *Use of a professional consultant in those tasks that the building department lacks expertise. Outsourcing does not reduce the building department's responsibility in the project.*
- *The lead designer is responsible for the overall project design:*
 - *Performance targets for structural, electric, HVAC, and automation design processes.*
 - *Coordination of design tasks to ensure the overall energy efficiency targets of the project.*
 - *The lead designer keeps the building department up to date on the design work*

progress and its implications on the building's life cycle performance indicators.

Summary

In this chapter, an example of how to incorporate energy efficiency in the public procurement process has been introduced. The procurement process has been extended to cover also a building's life cycle, to point out the connection between the decisions made during the actual procurement process, and the performance values which contribute to energy efficiency, indoor air quality, and life cycle economy of a building.

Energy Pricing for Households for Promoting Energy Efficiency

Samuli Honkapuro and Mika Luoranen
LUT University, Lappeenranta, Finland

Description

The energy pricing of a household customer includes pricing of the energy content (electrical energy in this case), pricing of the use of energy carriage network infrastructure (power grid, in case of electrical energy), and taxes, including energy taxation and value added tax. All these components could and should provide customers with incentives for energy efficiency.

In electricity markets, energy sales is typically opened for competition during deregulation, while electricity network operations remain in natural monopolies. These two sectors are different by nature, and thus, different pricing principles should be applied in each sector.

In energy wholesale markets, price is typically highly volatile, reflecting the varying output of the low marginal cost renewable generation. Pricing signals from wholesale markets should be passed toward end users to provide them incentives to use energy during the moments when there is abundant low-cost energy available, that is, during the low-price hours.

In network operations, the most suitable solution would be pricing method, which includes energy fee (cnt/kWh), peak power-based power fee (€/kW), and fixed stand-by fee (€/month). This would provide customers with incentives to efficient use of energy and decrease of peak power, while ensuring cost recovery for distribution system operator. Hence, such pricing is incentivizing efficient and sustainable use of energy.

Introduction and Background

The key objective for end users' energy bills is obviously to ensure cost recovery of the energy

system, including capital and operational expense of the generation facilities, fuel costs, emission allowance costs, costs of the network infrastructure, etc. This is ensured by having an appropriate price level that leads to reasonable revenue of the companies. However, intentionally or unintentionally, pricing also directs end users to adjust their energy usage so that their bill decreases.

For instance, if end users are charged by a fixed monthly fee (i.e., €/month), they pay the same price, no matter what is the amount of the consumed energy, and hence, such pricing system does not provide incentives to decrease the amount of energy consumed. However, if we provide certain price for the energy (i.e., €/MWh) and customers are charged by the amount of energy they consume, they get savings by decreasing energy usage, which will incentivize energy savings and energy efficiency improvements. Nevertheless, if we consider the issue from the system perspective, constant energy price might not be enough for optimal energy efficiency incentives, but optimal timing of the energy use and incentives for cutting the peak power should be also considered. This issue, that is design of the pricing from sustainability and energy efficiency viewpoint, will be discussed in this entry. Focus here is on the pricing of the electricity, which consists of energy price and network fee. However, similar principles can be applied as well, when planning the pricing of other energy vectors, such as heating, cooling, or gas.

Energy Pricing for a Household

Typically, energy pricing of a small-scale customer, such as a household, consists of price of consumed energy, network fee, and taxes. All these could and should be designed so that there are incentives for energy efficiency improvements, that is, efficiency gains of a customer will lead to lower energy bill for them. However, at same time, it should be kept in mind that certain costs, such as amortization of the capital investments, are fixed. If pricing is not cost-reflective, it may happen that increasing energy efficiency in customer end decreases the energy bill of the customer, but does not have effect on the costs of the utility. In such a case, if it happens in large scale, utility is forced to increase its prices to ensure cost recovery, and economic feasibility of the customer-end energy efficiency investments are jeopardized. Hence, cost-reflectivity of the pricing is highly important to ensure that actions that customers are incentivized to carry out, are benefitting both utility and customer, in both the short and long run.

In deregulated electricity markets, electricity generation (wholesale market) and sales (retail markets) are or can be opened up for competition to have efficiency gains. In electricity transmission and distribution, again, natural monopoly is emphasized, as it would not be an efficient solution to build parallel networks. Typical organization of the industry before and after deregulation process is illustrated in Fig. 1. Deregulation of the

Energy Pricing for Households for Promoting Energy Efficiency,

Fig. 1 Organization of the electricity industry before (left) and after (right) deregulation of the electricity markets

industry has taken place worldwide after the beginning of 1990s. However, the present situation varies between market areas.

Pricing of the Energy in Electricity Markets

The key technical requirement of the power system is to maintain balance between supply (generation) and demand (load) at every moment. Similarly, in heating system, energy balance must be maintained, but in the case of the district heating, there is natural energy storage in the network, which means that momentary balance is not necessary, but balance is important in daily and hourly basis. Power system balance is typically maintained by dispatching of generation so that it meets the demand at every moment. However, as intermittent renewables (wind and solar) are accounting increasing share of the generation, there is need for demand side actions also for constant power balance maintenance. These demand side actions are called demand response (DR) or demand side management (DSM).

Wholesale electricity markets are typically organized as a power pool or exchange, where

actors can sell and buy electricity organized without counterparty risk. In day-ahead (DA) markets, energy is bought and sold for every hour of next day, while in intra-day (ID) markets, trading can be done 30–60 min before operating hour. Balancing and reserve power markets are used by system operator for real-time balancing of the supply and demand during the operating hour.

Pricing is usually based on auction, either by pay-as-bid or marginal pricing. Marginal pricing is mostly applied to promote cost-efficient equilibrium of demand and supply, by directing merit order so that generation is brought online in the order of the prices (low cost generation first), until the electricity demand is met. Marginal price, equal to all participants, independent of the actual offer/bid, is in the equilibrium of the supply and demand bids, illustrated in Fig. 2.

This type of pricing reflects the variation in the variable costs of the electricity generation. In moments when there is abundant amount of renewable (e.g., wind and solar) generation available, price is very low, as their variable cost is close to zero. However, when there is scarcity of the supply, price may peak, reflecting high costs of the supply, price may peak, reflecting high costs of the supply, price may peak, reflecting high costs of the supply (e.g., gas turbine in figure below). Hence, this type of pricing provides

Energy Pricing for Households for Promoting Energy Efficiency, Fig. 2 Price formation in wholesale market of the electricity (marginal pricing)

incentives for efficient use of resources. Seller's surplus, that is difference between marginal price and variable generation costs, ensure recovery of fixed costs. Marginal price also provides long-term investment signals, as price levels increase if there is scarcity of the generation resources. Trading is typically in hourly resolution, so that energy is bought/sold for a specific hour. Hence, price varies between hours, and volatility might be high, especially if there is significant amount of intermittent renewable generation. Trend is that time resolution in markets is increasing and markets are moving toward real time. For instance, in EU there is regulation to move from 1 h to 15 min balance settlement period (EU 2017).

However, this type of marginal pricing is applied only in wholesale market. Small-scale customers, such as households, typically pay constant price, in which the price of energy is constant during the contract period (e.g., 1 year), and wholesale prices reflect the retail prices only by changes in long-term price levels. Time-of-use (ToU) tariffs have been applied in many cases, but they have limited steering effects, as they typically incentivize shifting the loads from daytime to nighttime, but they do not take into account actual system state and varying output of the renewables or volatility of the wholesale price. Hence, the so-called real-time pricing, which is based on hourly prices and real-time measurement of the consumption of the energy, would incentivize shifting of consumption to low-price hours. Such pricing requires Advance Metering Infrastructure (AMI), also known as smart meters, being installed. For instance, in Finland every customer has a meter that measures hourly energy consumption and is remotely read once a day. Such metering infrastructure enables real-time pricing, and at the end of year 2018, about 9% of Finnish electricity customers had real-time priced electricity supply contract (Finnish Energy Authority 2019).

End user pricing based on varying wholesale market price incentivize implicit demand response of the consumers, as it provides benefits if customer cut loads during price peaks and/or shift loads from high price hours to low price hours. Typically, time shifting of the loads require

that there is either storage incorporated to load (e.g., heating and cooling, in which buildings provide natural heat storage capacity) or that customer is willing to change his/her daily routines. However, to ensure that flexibility of the demand lead to lower costs of the energy, flexibility should be included in the demand bidding in wholesale markets. If customer reacts to price signal of the wholesale markets after market closing, it might, at least in theory, have impacts on system balance, which increase the costs, as illustrated by Nardelli and Kühnlenz (2018). Furthermore, if customers move significant part of their consumption to low price hours, it may lead to congestions in local network, as Belonogova et al. (2013) have illustrated. However, this latter challenge can be eased by planning the pricing in electricity distribution so that it incentivizes customers to avoid load peaks. This is further discussed in following section.

Network Fee

As discussed above, although generation and sales are opened for competition during deregulation of the electricity sector, networks are recognized as natural monopolies. To prevent misuse of the monopoly, and to provide network companies with incentives for improvement of efficiency and quality of supply, they are regulated by authority. Regulation may focus on profits (rate-of-return regulation), prices (price cap), or revenues (revenue cap). Furthermore, they can include benchmarking elements (yardstick regulation). In practice, regulation is hybrid, containing elements from different theoretical models. Regulation methods vary from country to country as they are decided by national authorities. In some countries, prequalification of the network fees (tariffs) by regulator is required *ex ante*, while other countries let the network companies freely decide their price structures, and check *ex post* whether revenue or profit is below the cap. In any case, regulated companies are provided with regulatory framework; that is principles of defining of the revenue/price/profit cap. Typical approach, applied, for instance, in Finland, is to allow certain

rate of return and reasonable level of depreciation for network assets to ensure the companies can invest in network, and define reasonable level of operational expenses based on historic level of costs and certain annual efficiency improvement requirement. Inflation and some costs that are outside of the control of network company are typically treaded as pass-through cost items.

From the energy and resource efficiency viewpoint, network fee should provide energy end users with incentives to adjust their energy usage so that it does not cause increase in peak loads of the network that may lead to bottlenecks and reinforcement needs of grid. In theory, this would mean that price would vary based on the network load. However, in addition to monopoly

regulation, there are a number of constraints and drivers in planning of the network pricing. One of the constrains is spot pricing (aka point tariff), which means that price should not depend on the location of the customer within network area. This is a similar approach as in postal stamp tariffs; the customer is entitled to use the network in whole country or market area by a single tariff. Because of these constraints, theoretical optimal solution may not be feasible for practical implementation.

In addition to the above described, there are various criteria that should be taken into account in distribution tariff design. Key criteria for distribution network pricing have been illustrated by Honkapuro et al. (2017), see Table 1.

Energy Pricing for Households for Promoting Energy Efficiency, Table 1 Summary of the criteria for distribution tariffs (Honkapuro et al. 2017)

Criterion	Description
Cost-reflectivity	In this context, “cost-reflectivity” means that the distribution tariff structure reflects the cost structure of the distribution system operator within the limits of spot pricing. This supports fairness and neutrality of the tariffs for different customers. Further, the distribution tariffs shall generate sufficient revenue to ensure the operating conditions of the distribution system operator
Neutrality for third parties	This criterion indicates that the distribution tariff structure should not constrain or prevent the operation of third parties. Further, the primary objective of the distribution tariffs is not to generate new business options, e.g., for demand response services but rather ensure that the distribution tariff does not constrain the future operation of these third parties within the technical limits of the distribution system
Steering effects/Incentives for efficient use of electricity	The core idea of this criterion is that the distribution tariff is one of the components in incentivizing the customer for resource efficient use of electricity. In the long term, this will lead to a reduction in the total costs of the electric power system. The distribution tariff allows the customer to affect the amount of her/his distribution fee by her/his own actions and decisions
Feasibility of practical implementation	“Feasibility of practical implementation” means that the tariff structure can be implemented at a reasonable cost. The practical implementation of the basic functions of the tariff should be cost efficient and, as far as possible, realizable with the present and foreseeable systems and infrastructure (e.g., next-generation metering and ICT systems) in order not to cause unreasonable costs to the distribution system operators and customers. In the new tariff structure, also customer communications and contacts with customer services have to be taken account of initially or annually, e.g., if the power threshold is changed
Compliance	“Compliance” means that the tariff structure is not in conflict, e.g., with the present but also potential new tariffs provided by the electricity retailer. This criterion shall also take account of third parties’ future development trends in pricing
Intelligibility	“Intelligibility” means that the tariff structure, in other words, the set of rules according to which the customer’s distribution fee is determined, is consistent and simple enough as a whole. Based on the price list, the customer has to be able to comprehend the rationale behind her/his distribution fee without unreasonable effort

As we can see from the table above, there are multiple criteria, and some of them might even be contradictory. For instance, if the aim is to have good cost-reflectivity, the price structure has to contain various dynamic elements, and it becomes highly complex, which is opposite to intelligibility criteria.

Honkapuro et al. (2017) have arrived at a conclusion that network fee structure, which fulfills the above illustrated objectives, would be power-based pricing combined with energy-based and fixed fee. Such pricing includes a price component, which is based on the customer's measured peak load (€/kW), energy-based price component (cnt/kWh), and a fixed monthly fee (€/month). This would provide users with incentives to decrease their peak loads and energy consumption, of which both actions promote energy efficiency. Furthermore, such pricing would ensure stable incomes and adequate cost recovery for distribution system operators (DSOs). In theory, network pricing should be similar in consumption and production, that is, customer should be charged by same fee, if he/she is taking electricity from grid, or feeding it to grid. However, typically, in society, there is willingness to incentivize renewable micro-generation, and hence, network fee for micro-generation is inexistent or very limited.

Summary

The energy pricing of a household customer includes pricing of the energy content (electrical energy in this case), pricing of the use of energy carriage network infrastructure (power grid, in case of electrical energy), and taxes, including energy taxation and value added tax.

In electricity markets, energy sales is typically opened for competition during deregulation, while electricity network operations remain in natural monopolies. These two sectors are different by nature, and thus, different pricing principles should be applied in each sector.

In energy sales, wholesale price is typically formed based on the bids of the sellers and buyers. Marginal price reflects the varying cost of the most expensive generation form, which is needed

to fulfill the demand during an operating hour. This pricing method is promoting efficient use of the primary energy resources, as lowest variable costs is typically in those generation form, which does not have fuel costs (i.e., wind and solar). Price is highly volatile, especially if there is a significant amount of variable renewable generation in system. Customers should be provided incentives to use energy during the moments when there is abundant low-cost energy available, that is, during the low-price hours. However, it has to be ensured that customers' demand response do not increase system balancing costs.

In network operations, pricing is typically somehow regulated by the authority, to avoid the misuse of the monopoly position. Regulation may focus directly on prices, or on the revenues or profits. In this sector also, pricing should promote efficient use of infrastructure, in this case power distribution and transmission networks. In addition to that, pricing has several criteria, such as cost-reflectivity, neutrality, intelligibility, and it has to be feasible to implement. Based on recent research results, it seems that the most suitable solution would be the pricing method, which includes energy fee (cnt/kWh), peak power-based power fee (€/kW), and fixed stand-by fee (€/month). This would provide customers with incentives to efficient use of energy and decrease of peak power, while ensuring cost recovery for distribution system operator. Hence, such pricing is incentivizing efficient and sustainable use of energy.

However, when developing and introducing novel pricing schemes, it should be taken care that these pricing schemes do not cause energy poverty, and vulnerable customers, who may have difficulties to comprehend and follow the pricing incentives, are not preyed on. Important actions here are providing information and long enough transition periods for price changes.

Definition/Description

Energy is defined renewable energy (RE) if it is gained from sources which are not depleted by use or if the sources can be recovered in human time scale. In contrast to nuclear and fossil fuels, which are in principal limited resources (BGR 2017), renewable energy is infinitely available in a time frame relevant for humanity (Quaschnig 2016). Limitless sources for energy are geothermal energy, planetary energy, and solar energy.

Introduction

Availability of energy for heating, communication, illumination, and other purposes is crucial for modern societies and economies. Therefore, the security of energy supply is important. Increasing population and increasing standards of living led and lead to a continuous increase of energy consumption (BP 2019a). An increase of the global energy demand by more than one quarter (IEA 2018a) to around one third (BP 2019a) of today's demand by 2040 is expected due to the "increase in living standards, especially in India, China and whole Asia" (translated from BP 2019a). In the same press release, it is stated that renewable energy and natural gas contributes to the increase of energy supply by 85% and that electric power in 2040 will be mainly produced by renewable energy.

Why renewable energy? Climate change (see ► [“Climate Change”](#)) caused by increasing greenhouse gas emission (see ► [“Greenhouse Gas Emissions”](#)) was already identified as a major challenge in the 1980s (IPCC 1990). Carbon dioxide was identified as the most important factor for global warming (Hansen et al. 1981; IPCC 1990) (see ► [“Carbon Emissions”](#)).

Using energy from renewable sources has therefore got two benefits: In contrast to limited resources like fossil and nuclear fuels, sources of renewable energy are indefinite and the emissions of greenhouse gases only needs to be considered during the manufacturing, installation, and deconstruction phase of the plants for energy transformation. Application of wind, hydro, and solar power does not lead to greenhouse gas emissions, since no combustion or other chemical processes releasing greenhouse gases (GHG) take place. In case of bioenergy, there is only emission of CO₂ which was recently absorbed by the plants used for the bioenergy production. If new plants are grown to replace the plants used for bioenergy, it is assumed to be carbon neutral (Dunlap 2015, p. 393; Quaschnig 2016). In contrast fossil fuels contain carbon which was stored millions of years ago in plants and is now released by combustion as CO₂ (Dunlap 2015, p. 64.). Additionally mining of fossil fuels can lead to methane emissions, a powerful greenhouse gas (Quaschnig 2016) (see ► [“Greenhouse Gas Emissions”](#)).

Classification of Renewable Energy Due to the Sources

Solar

The sun is the most important source of renewable energy as it provides solar radiation. Solar radiation is transformed into heat by natural conversion. Due to differences in temperature, caused by inhomogeneous heating of the earth, wind is generated. The water cycle also depends on solar radiation, since solar heat causes the evaporation of water which is then condensed and precipitated in colder parts of atmosphere. Solar radiation is also necessary

for the production of vegetable biomass by photosynthesis.

Solar radiation is most intensive near the equator in the desert regions, where cloud formation is low. Most favored regions can be found in Mexico, the south of western USA, in the Andes regions of Peru, Chile and Argentina, northern Africa, the Arabian peninsula, Iran, Afghanistan, parts of China, and Australia (World Bank Group 2016). For the sustainability of solar power plants, see ► [“Sustainability and Solar Energy”](#).

Solar Thermal Energy

Solar radiation can be transformed into heat, which can either be used directly for heating and hot water supply (Streicher 2007) or, if heat levels are high enough, for the production of power by steam power plants (Weinrebe and Ortmanns 2007). For heating and hot water supply, flat plate collectors and vacuum tube collectors can be employed, which provide low to medium temperatures (ome 2012). In 2010 the total installed capacity of flat plate collectors and vacuum tubes was 200 GWh of thermal energy. Most of the installations were found in China, which had the highest share with 59%, followed by Europe with 13% and North America (USA and Canada) with a share of 8% (ome 2012).

Steam production requires higher temperature levels which can be achieved by concentrating solar radiation by solar collectors, lenses, or mirrors of different geometries (Weinrebe 2007). Linear collectors, mostly parabolic troughs which focus the sunlight on an absorber tube, are produced already in series. Fresnel collectors which consist of individually positioned distributed mirrors can also be applied (Quaschnig 2016). To get even higher temperatures, point concentrators are used which focus the sunlight on two axes. Mirrors with dual axis trackers that focus the sunlight optimally are called heliostats (Quaschnig 2016).

The generated steam can be used in the same way as steam in conventional steam power plants powered by fossil or nuclear fuels. Since storage of heat is technically feasible, this type of power plant can produce power on demand and during night time (Quaschnig 2016; TREC 2007). If

longer periods without sufficient sunshine are expected, the operation as a hybrid power plant is possible (DLR 2006). Concentrated solar power plants can be combined with biofuels as alternative heat source, for example.

In the Desertec concept (see ► “Desertec”), concentrated solar power plants (CSP) were the key element for the production of reliable power on demand (TREC 2007). Although the Desertec concept was abandoned in 2014, it helped initiating the construction of big CSP installations in Northern Africa. In 2016 the first phase of the biggest CSP plant worldwide with an expected capacity of 500 MW was launched in Ouarzazate, Morocco (World Bank 2016). Parabolic troughs were used for Noor Ouarzazate I and Noor Ouarzazate II. In the third installation, Noor Ouarzazate III, heliostats were used to concentrate the solar light on a tower. Noor Ouarzazate III has a gross production capacity of 150 MW and a storage capacity for thermal heat of 7.5 h of production (SolarPaces 2018).

Photovoltaic Power Plants

In contrast to solar thermal power plants, photovoltaic (PV) cells convert solar radiation directly into electric power by photovoltaic effect (Kaltschmitt and Rau 2007). Diffuse and direct radiation can be used to produce power without intermediate heat production. PV cells are produced as single cells, which are assembled in modules, also described as PV panel. A parallel or serial configuration of the cells is possible, but usually a serial assembling is preferred, since it can increase the voltage without increasing the current. The modules can also be combined – either in series or in parallel. PV cells produce direct current (DC) but most applications and the connection to the grid usually require alternating current (AC) for power supply. Therefore DC-AC converters – so called inverters – are applied to connect PV-panels to the grid or load (Twidell and Weir 2006).

Due to their modular composition, PV plants are scalable (Twidell and Weir 2006; Moore and Post 2008). Applications vary from small portable devices to installations of several MW. The largest single location photovoltaic park in 2017 was the

Kurnool Ultra Mega Solar park with 1000 MW Peak power (Statista n.d.; Jaiswal and Bhagavatula 2017). In contrast to solar thermal power plants which allow for the option to store heat, the power production of PV panels depends directly on solar radiation. This means that the power production is at its highest during noon and a high fluctuation depending on cloud formation can be observed. The high variation in power supply can be a challenge for the integration of PV power (Hashemi and Østergaard 2016). Depending on national regulations, the inverters connecting the PV modules to the grid require the option to actively reduce power supply when the grid is overloaded.

Wind Energy

The idea of transforming wind energy into mechanical energy that can be used for pumping (Taylor 2012, p. 302), drainage (Quaschnig 2016), or propelling ships (Ellabban et al. 2014) is quite old. In the age of steam engines and electrification, the use of wind power became less important (Quaschnig 2016). It was due to the oil crisis in the 1970s that wind power came back into focus. Today it is used almost exclusively for power generation.

Modern wind power plants have got a rotor which starts rotating as soon as it interacts with wind. We can distinguish two main types of wind turbines: horizontal axis and vertical axis machines (Twidell and Weir 2006).

Vertical axis machines can accept the wind from any direction without needing adjustment to the direction of wind. Since the wind power plants are not exposed to gravity induced strain, they could be very large in principle (Twidell and Weir 2006). But vertical axis machines often experience resonance in structure which can cause fatigue failures, and the torque of the wind can vary periodically, which leads to unwanted power periodicities in power output. Depending on the rotor type, the driving force is either drag or lift or a combination of both.

Horizontal machines can be differentiated further into upwind installation, in which the rotor meets the wind before it reaches the tower or downwind installations, in which the wind first

meets the tower and then the rotor. The last one is in principle self-orientating but has the disadvantage, that the tower in upwind position shades the blades. This causes extra wind turbulences in the path of the blades and leads to additional strain on the blades (Twidell and Weir 2006).

Upwind horizontal axis machines have to be adjusted to the wind, either by a tail or by a yawing mechanism. The dominant driving force is lift and the blades are constructed like airplane wings (Twidell and Weir 2006). Most common are upwind horizontal axis machines with three bladed rotors, since they operate more smoothly and quietly than two bladed rotors. Since the material demand increases with the number of blades, three-bladed turbines are the most effective solution for wind power plants (Twidell and Weir 2006).

To prevent an overload of the wind power plant at high wind speeds, the rotor speed is controlled either by a passive mechanism using the stall-effect or by active control that adjusts the blades using electric motors (pitch-control) (Quaschnig 2016).

To transform the kinetic energy into electric energy, an electric generator is necessary. To adjust the rotation of the wind turbine rotor of 15–20 rpm (round per minute) for a 1 MW turbine to the rotation of the generator of 1800 rpm, it requires gears (Salameh et al. 2018). But since they are exposed to high strain, they require much maintenance and the failing of one component would lead to a stop of power production. This is why wind power plants that operate without a gearbox have been developed in the last 10 years (ENERCON 2016).

Synchronous or asynchronous generators are employed for electricity production (Kaltschmitt et al. 2007a). Synchronous generators have a slightly higher efficiency but cannot be connected directly to the grid, since gusty wind can cause high strain (Kaltschmitt et al. 2007a). Asynchronous generators, also called induction generators, can be operated more flexibly by using a variable slip (slip denominates the difference between speed of stator and rotor). This allows for a better adaption to an inflexible grid (Quaschnig 2016), but leads to losses of efficiency.

Wind power plants only produce power when the wind blows, which makes preplanning of power production difficult. The power generation of wind power plants is proportional to the wind speed cubed, so areas with high wind speed are favored. In order to avoid turbulences, flat areas where roughness is not affecting wind speed and causing turbulences as well as mountain tops are optimal for the installation of wind power plants (Schaffarczyk 2012). In recent years, off-shore installations became more important since higher and more constant wind speed are observed here. Since the generated power of wind power plants increases with size, bigger plants are favored. The size of wind power plants has increased significantly in recent years. The average nominal power increased from 1.6 MW in 2009 to around 2 MW in 2014 (IRENA n.d.-a); in 2016 Enercon offered wind turbines with nominal power above 7 MW (ENERCON 2016).

Like other renewable power plants, wind power plants also have a negative impact during operation (Kaltschmitt et al. 2007b). Sound emissions during operation were an issue which could be reduced by technical measures like optimal wind energy converter design. The effects of infrasonic sounds were discussed but since certain distances to buildings have to be observed, also in order to minimize the effect by shadowing and disco effect by rotation of the blades, this has no measurable impact on population (Kaltschmitt et al. 2007b).

Negative impacts on birds and bats are widely discussed but a quantification of the impact on their population level is difficult (Diffendorfer et al. 2017). In many countries, Environmental Impact Analysis is required before installation, also in order to avoid negative impacts of wind energy converters on protected bird and bat species.

Hydropower

The potential energy of water in rivers can be used in hydropower plants for the production of electric power. Slopes are required to use the potential and kinetic energy of water, so this form of renewable energy is only available in mountainous regions

with rivers. Up to now this form has the second highest share of renewable energy in primary energy consumption (IEA 2019). Hydropower plants can be classified as run-of-river, storage, and pump storage.

Run-of-river hydropower plants gain the energy for electricity production from the flow of a river. Electricity production therefore strongly depends on the local river flow conditions and substantial daily, monthly, or seasonal variations are possible (Ellabban et al. 2014).

Storage hydropower plants have a water reservoir which enables power supply independent of the variability of the river flow. They also allow power supply on demand. Setting up a storage hydropower plant requires dam building. Usually the dam consists of concrete and steel. Both materials require a high amount of energy for production. Concrete also releases carbon dioxide during hardening (see ► “Carbon Emissions”). So in the construction phase, high amounts of carbon dioxide can be released.

Depending on the size of the reservoir, land is flooded which means that it is lost for settlements, farming, and wildlife. During the flooding process, plants are degraded by anaerobic decomposition, with the consequence that the very potent greenhouse gas methane is released (see ► “Greenhouse Gas Emissions”) (Demarty and Bastien 2011). To assess the whole impact of hydropower plants, environmental impact assessments are required (see ► “Environmental Impact Assessment”).

Pump storage hydropower plants are no energy sources but devices for the storage of electric power. If excess electric power is available, water is pumped into an upper reservoir. When additional electricity is needed, the water is released from the upper reservoir into the lower reservoir so that it drives turbines for electricity production (Quaschnig 2016).

In order to convert the kinetic energy of water into the kinetic energy of the turbine, different types of turbines for different amounts of flow rate and slope were developed. Impulse turbines, like the Pelton turbines, use the kinetic energy of the water. Reaction turbines, like Francis turbines, are driven by varying water pressure (Quaschnig

2016). Francis turbines can also be used to pump water and therefore they are often used in pump storage hydropower plants (Twidell and Weir 2006). In midsize to large hydropower plants, several turbines are operated in parallel. So individual turbines can be switched off, if not enough water flow is available or the demand drops. The goal is that the remaining turbines operate at their nominal power output (Quaschnig 2016). The efficiency of these turbines for the transformation of the kinetic energy of the water into kinetic energy of the turbine can be quite high (80–95%). The efficiency of a synchronous generator can be between 90% and 95% for small to medium sized installations and 95% and 99% in large plants (Jorde and Kaltschmitt 2007). Usually synchronous generators are used to produce electric power (Quaschnig 2016), but asynchronous generators are also suitable (Jorde and Kaltschmitt 2007).

Wave Energy Converters

Another option to use water energy is the usage of wave energy, but its conversion into electric power is only just being developed (Uihlein and Magagna 2016). Up to now no commercial power plants are in operation.

Bioenergy

Solar radiation also enables the growing of plants and the production of biomass. Biomass like wood can be directly used for heat production. Alternatively, thermo-chemical or bio-chemical processes can convert biomass into biofuels like charcoal, biodiesel, ethanol, or biogas, which can substitute conventional fuels like coal-briquettes, diesel, gasoline, or natural gas (Ellabban et al. 2014).

Biofuels can be differentiated by the phase state of the biofuel which is either solid, liquid, or gaseous. Another common classification differentiates between primary biofuels (derived from plants which are also used for food production like sugar cane, corn, vegetable oil), secondary biofuels (derived from plant residuals or plants which are not used for food production), and tertiary biofuels derived from algae (see ► “Algae Bioenergy”).

According to IEA, bioenergy has the highest share of all renewable energy forms with 9% share of the total primary energy supply (TPES) (IEA 2017).

The traditional biofuels wood and charcoal (derived from wood) are mostly used in developing countries for *“for cooking and heating, using inefficient open fires or simple cookstoves”* (IEA 2017 Bioenergy and biofuels) and have a share of 55.4% of the global bioenergy use (IEA 2017), while nontraditional heating-systems have a share of 24.7%. 12.4% of bioenergy is applied for electricity production and 6.3% for transportation (IEA 2017).

The most important modern biofuels are biogas derived from plants and manure (Meyer et al. 2018), biodiesel derived from vegetable oil (Widmann et al. 2009), and ethanol derived from starch and sugar containing plants (Senn et al. 2009). Compared to other renewable energy sources like wind and solar energy, biofuels have the advantage that they can be stored as conventional fuels (Ellabban et al. 2014).

The sustainability of bioenergy is controversial, since the use of arable land for biomass production competes with other uses like food, paper, and wood production (Morris and Scurlock 2012). Deforestation, greenhouse gas emissions by land use change (see ► *“Greenhouse Gas Emissions”*), and impact on soil quality are other factors which have to be considered (IPCC 2017). In dry areas, water that is used for irrigation can also be an issue (see ► *“Water”*). The incineration of biomass or biofuel only releases the carbon dioxide which has recently been taken up by the plant. But the growing and harvesting of plants requires energy, which might come from fossil fuels and this leads to an additional emission of carbon dioxide. Industrial fertilizers, based on nitrogen, are produced by the Haber Bosch process, which requires a high amount of energy and hydrogen which is usually derived from natural gas. In soil, denitrification can lead to emissions of nitrous oxide which is a very potent greenhouse gas (see ► *“Greenhouse Gases”*).

Geothermal

Geothermal energy is the heat energy inside the earth. The core of the earth has a temperature of around 4600 °C (Quaschnig 2016). In contrast to the high temperature of the core, the crust has got a low temperature. When going deeper, the temperature level quickly increases. By drilling, high temperature levels can be accessed, best in regions with geothermal anomalies, which can be found in Iceland, Italy, USA, Mexico, New Zealand, and Philippines (Quaschnig 2016). The heat can be used directly for heating, for the operation of heat pumps, or – if temperature levels are high enough – for the production of electric power (Dunlap 2015, pp. 380–385). At the beginning of the century, Iceland’s geothermal energy had a share of 55% of the primary energy consumption, providing 87% of the heat demand and 18% of annual power production (Gunnarsson 2002). In contrast to other renewable energy forms, it is not indefinite, since the heat removed from the reservoir is removed faster than it can be replenished by the heat flow from the interior. Depending on the size of the reservoir and the amount of heat that is removed, the lifetime of a heat reservoir can vary between a few and several 100 years (Dunlap 2015, p. 388). Power production by geothermal energy is projectable.

Planetary

Since the tides are caused by planetary attraction, using the energy of tides for power production is related to planetary energy. In contrast to waves, tides can be predicted with high certainty. But the number of places where the tidal range is high enough for energy harvesting is limited. Since the installations have to be close to the coast, the installation of energy conversion systems has a high impact on the environment. Up to now only few commercial power plants in Canada and United Kingdom are operated with tide power (Dunlap 2015, p. 350).

Relevance of Renewable Energy for the Energy Supply

“Hydroelectricity, wind and wave power, solar and geothermal energy and combustible renewables and renewable waste (landfill gas, waste incineration, solid biomass and liquid biofuels) are the constituents of renewable energy.” (BP 2019c). In contrast to fossil and nuclear fuels, for which the consumed or supplied amount of primary energy can be measured, renewable energy as primary energy occurs in free floating form. *“There is no single, unambiguous method for calculating primary energy from non-combustible energy sources such as non-combustible RE sources and nuclear energy”* (IPCC 2012, p. 10). Different methods are used to estimate the amount of primary energy sources. The IPCC for example uses the direct equivalent method, in which fossil fuels are accounted by their heat value, while renewable energy sources are accounted by the secondary energy (e.g., electricity) they produce (IPCC 2012, p. 10).

This method is also used in the Statistical Reviews of British Petrol. Hydropower, for example, is reported as consumption of hydroelectricity and biofuels have been included in oil consumption. The consumption of renewables for heat production has been excluded until now in the statistics of British Petrol (BP 2019c), while the International Energy Agency considers biofuels also for heat production. That is one reason for the deviation in share of renewable energy in primary energy consumption and supply of their statistics. Including heat production by biomass the International Energy Agency got a share of 14% in the total primary energy supply (IEA 2019) while BP, excluding biomass for heat production got a share of renewable energy of around 11% (BP 2019b) in the world's energy consumption.

A share of renewable energy around 14% is not much. Highest additions were obtained in the power sector, in which the share of renewables increased by 70% in 2017 (REN21) to 23.9% according to IEA (IEA 2018b). In the sector “heating” the share of renewable energy was

10.3%, in the sector transport the share of biofuels was 3.4% (IEA 2018b). The sector “cooling” was not announced. These sectors accounted for 80% of the global final energy demand (REN 21 2018). But they showed only small or no increase of renewable energy and only small increase of shares are expected (IEA 2018b).

As already mentioned, bioenergy has the highest share of all renewable energy forms with 9% share of the total primary energy supply (TPES) (IEA 2017). The second most important renewable energy is hydro power, the only renewable energy which has increased by 2.8% within the last 10 years (BP 2019b).

The most significant increase of renewable energy for power production was observed for wind energy: Installed capacity for wind power production has been increased from 178 GW installed capacity on-shore to 540 GW on-shore between 2010 and 2018 (IRENA n.d.-a). Additionally around 23 GW have been installed off-shore in 2018 (IRENA n.d.-a). In 2016 around 957 TWh of electricity were produced by wind power (IRENA n.d.-a).

Electricity production using solid biomass was around 372 TWh, using biogas 87.5 TWh, and using liquid biofuels 6.9 TWh (IRENA n.d.-b). Photovoltaic power plants produced around 300 TWh in 2016, CSP around 11 TWh (IRENA n.d.-c).

Sustainability of Renewable Energy Installations

Depending on the size of renewable energy installations and national regulations, an environmental impact assessment is required (see ► [“Environmental Impact Assessment”](#)). For a complete analysis of energy efficiency, resource efficiency, the impact on human health and environment, and the emissions of greenhouse gases, a life cycle analysis has to be performed (see ► [“Life Cycle Analysis”](#)). For an assessment of sustainability of installations of renewable energy, see ► [“Sustainable Energy”](#) and in case of solar energy ► [“Sustainability and Solar Energy”](#).

Summary

Even though the traditional use of biomass for heat is still most important, other forms of renewable energy like hydro, wind, modern bioenergy, and solar energy have become more relevant in recent years and a further increase is predicted.

In principal, renewable energies could guarantee indefinite energy supply with low or no carbon dioxide emissions. Only in the construction and deconstruction phases and in case of maintenance, carbon dioxide emissions can be significant. But the share of renewable energy which can be efficiently transformed into useful energy such as heat, electric power, or other forms depends on local conditions. Biomass is assumed to have the highest potential but the use of biomass for energy generation competes with its use in food production, and in the production of other goods made from plants. It also affects biodiversity. Hydropower plants consist of established technologies. In many countries, hydropower plants have been in operation for several decades but social impacts like the resettlement of villages, the impacts on landscapes, or on ecologically important sites can be quite high. Flooding can also lead to high methane emissions, when the area is not cleared of plant material before flooding.

Wind energy and the use of solar power have the advantage of lower impacts on ecological systems and less land-use but they highly depend on weather conditions and the prognosis of power production is difficult. Therefore, storage systems for energy will become more and more important.

In order to evaluate the sustainability of renewable energy forms, environmental impact assessments and life cycle analyses have to be performed.

Enlightened Self-Interest

Suvi Hirvonen-Ere

Department of Information and Service Management, School of Business, Aalto University, Espoo, Finland

Synonyms

Doing well by doing good; Self-interest rightly understood

Definition

Enlightened self-interest means a “self-interest rightly understood” where a person, a group, or an organization is “doing well by doing good.” These largely cited quotes are attributed to Alexis de Tocqueville regarding the first (Heffner 1956; Vearrier 2020) and often to Benjamin Franklin regarding the second. Helping others to achieve their interests is a premium manner to advance one's self-interest (Frimer et al. 2011).

The Merriam-Webster Dictionary defines Enlightened self-interest as “behavior based on awareness that what is in the public interest is eventually in the interest of all individuals and groups” (Merriam-Webster Dictionary 2022).

Corporate Social Responsibility (CSR) is a form of Enlightened self-interest (Keim 1978). The enlightenment of an organization is motivated by a self-interest, with the target to increase sales, strengthen the company brand, and inspire employees (Ptacek and Salazar 1997).

Background of the Enlightened Self-Interest

The background of the Enlightened self-interest is sometimes attributed to the religion-originated golden rule where one should treat others the way they wish to be treated themselves. Further, the background lies in the Age of Enlightenment, with thinkers such as Thomas Hobbes (Kavka

2021), Jean-Jacques Rousseau (Ptacek and Salazar 1997), and Adam Smith (Dwyer 2021). The synonym “self-interest rightly understood” refers to Alexis de Tocqueville (Heffner 1956; Vearrier 2020), and “doing good by doing well” is often assigned to Benjamin Franklin. Even before them, there are ties to the concept referring back to Plato and Aristotle at the era of the Ancient Greek (Xiang 2016).

At the beginning of this millennium, the Enron accounting scandal led to the largest bankruptcy in the history of corporate America and hit the Wall Street to its core (Healy and Palepu 2003). The aftermath of the Enron case questioned the business models and insufficient private corporate governance (Bratton 2001) as well as plain economic rationality and greed that are often considered as antonyms to Enlightened self-interest.

How to Implement Enlightened Self-Interest into an Organization?

Corporate social responsibility is an appearance of Enlightened self-interest. According to the European Commission, CSR is “a concept through which the company voluntarily integrates the social and environmental dimensions in its business operations and in its relations with stakeholders” (COM 2001 366).

Embedding (integrating) CSR into an organization is a way to implement the Enlightened self-interest approach into it. Embedded CSR occurs when organization’s core competencies are involved and the CSR is integrated throughout the company’s strategy, operations, and routines and thus impacting all employees, instead of peripheral CSR that builds upon philanthropic and voluntary activity (Aguinis and Glavas 2013).

Embedding CSR into an organization can be carried out by, among other things, deploying the standards of the International Organization for Standardization (ISO) (Valmohammadi 2014); by an organizing principle determined as “Discovery Leadership” and developing a corporate social responsibility performance model (Swanson 1995, 2008, 2014); and by utilizing existing methods in an expanded manner, such

as business contracts, contracting, and the contract management approach to promote the breakthrough of sustainability and incentivize the green economy (Hirvonen-Ere 2019). As the Enlightened self-interest approach underlies and in many cases motivates the corporate social responsibility course of action, these techniques could be applied, *mutatis mutandis*, to implement the Enlightened self-interest approach into an organization via embedded CSR.

In the networked economy, integrating values, such as Enlightened self-interest, in the business models of an organization is a success factor (Jansen et al. 2017). One solution to implement this into a profit or a nonprofit organization is via customization, innovation, and authenticity (Jansen et al. 2017). The relation between sustainability-oriented innovation and business models has been found important (Adams et al. 2016; Rohrbeck et al. 2013).

Among proposed solutions is cause-related marketing (CRM). CRM is the “corporate America’s lexicon for working in financial concert with a charity. It is marketing that ties a company and its product to a cause” (Ptacek and Salazar 1997, p. 9). One suggestion for CRM to further develop and reach the level of Enlightened self-interest is to perform it via “a properly designed CRM program” (Ptacek and Salazar 1997).

Why Does Enlightened Self-Interest Matter?

Simply put, organizations that apply Enlightened self-interest perform better than those who do not (Jansen et al. 2017; Meyer 2015).

While business models prevail over more traditional means to predict business outcomes, organizations that succeed in integrating values, such as those underpinning Enlightened self-interest, into their business models do better than those whose performance is based on the plain economic rationality (Jansen et al. 2017).

Regarding cause-relating marketing, the charity and the corporation engage in such a program due to mutual benefits. While a corporation committing to a CRM program desires increased sales,

elevated brand image, and sense of purpose among employees, the charity is in pursuit of funding, whereas the consumers crave social responsibility for a nice price (Ptacek and Salazar 1997).

However, it has been questioned whether doing good always leads to doing well and under which premises this could occur (Bhattacharya and Sen 2004; Busse 2016; Sen and Bhattacharya 2001).

If the company fakes doing good via sending pretended signals of their CSR activity (Siegel and Vitaliano 2007), the result may be the opposite and the company brand may suffer due to the company being perceived as a sham (Carlini et al. 2019; Scheidler et al. 2019).

Accordingly, regarding cause-related marketing, in case the elements relating to the charity, the corporation, and consumers that a duly designed CRM program would combine are left isolated, the result may be negative and be perceived as plain self-interest instead of Enlightened self-interest (Ptacek and Salazar 1997).

As an additional note regarding a relation between Enlightened self-interest, corporate social responsibility, and the corporate top management, a study among Asian manufacturing industry has found a relation between the company choice between embedded (integrated) or peripheral (philanthropic, volunteering) CSR and the top management behavior. Narcissistic behavior of the company CEO seems to lead to less integrated corporate social responsibility; companies with narcissistic CEOs seem to concentrate more to peripheral CSR instead of embedded CSR (Chen et al. 2021).

Future Research

One example of the areas of growing interest is the question of implementation (Adams et al. 2016). Another example is the search for a sustainability-related business model, at the same time questioning the current neoliberalistic ideology (Adams et al. 2016; Boons and Lüdeke-Freund

2013). Enlightened self-interest, corporate social responsibility (CSR), and embedded CSR are topics whose significance is likely to increase in the future. As these topics and their subcategories are broad, they offer several paths for future research.

Summary

The term Enlightened self-interest means “self-interest rightly understood,” a quote attributed to Alexis de Tocqueville, and “doing well by doing good,” a quote frequently accredited to Benjamin Franklin. At many occasions, the enlightened self-interest underlies and motivates corporate social responsibility. Companies that apply the Enlightened self-interest approach are often considered to perform better than those who apply plain self-interest build upon solely economic rationality. Companies that are doing good are doing well and better than those who do not.

Entrepreneurial Sustainability

Renato Civitillo
Department of Political Science (DISP),
University of Naples Federico II, Naples, ITALY

Synonyms

Business sustainable development; Sustainability in entrepreneurship

Definition

Sustainable entrepreneurship can be defined as an entrepreneurial action in which the production and exchange of goods and services represents an intermediate, or instrumental, goal in achievement different aims, both economic and non-economic.

In sustainable entrepreneurship, the concept of “gain” disregards the “economic” vs. “non-economic” bipartition tradition, to assume an autonomous space in which the focus on non-economic aspects does not compromise the achievement of purely economic objectives. In this sense, the non-economic targets are not considered as simple complements to those of an economic nature: it does not postulate a two-dimensional geometric space to be filled through a variable combination of the two types of objectives previously mentioned, but, on the contrary, it theorizes a multifaceted and three-dimensional concept of entrepreneurial space, which is interactive and

dynamic, and in which the two ideal elements of economic and non-economic purposes are not mutually exclusive but can be fed to each other, generating potential so-called win-win situations.

Introduction

Nowadays, one of the most discussed aspects, both at the academic and research level, and in the empiricism of the productive sector, is represented by the role of the entrepreneur and business organizations in modern economic systems.

Within the multitude of roles that the entrepreneur can embody, many have nothing or little to do with the constructive and innovative function that traditional economic theories conventionally attribute to this particular economic actor.

In this sense, Hobsbawm and Wrigley (1999) argue that:

It is often assumed that an economy of private enterprise has an automatic bias towards innovation, but this is not so. It has a bias only towards profit. It will revolutionize manufactures only if greater profits are to be made in this way than otherwise. (p. 18)

This means that the figure of the entrepreneur can also be represented, in the economic reality, with profoundly negative conceptual meanings, to the point of constituting – even – the emblem of a parasitic function (Baumol, 1996), in large of deeply damaging himself, the other entrepreneurs and, more generally, all the actors present in a given economic system (more or less widely, depending on the potentially generatable effects).

The central point of the discourse is that it must necessarily be recognized that entrepreneurship presents:

- An economic function, linked to the ability to create wealth or profit
- A social function, linked to the achievement of nonfinancial purposes

Following this distinction, the related ends may be different but, in any case, they can be referred to two main categories:

- Economic objectives, in which profit is included, in addition to many others.
- Social objectives, concerning the set of social, environmental, moral, and ethical purposes towards which each entrepreneurship naturally converges.

It is, however, useful to highlight that some authors (Baumol, 1996) believe, more specifically, that the effects resulting from the entrepreneurial action are specifically connected to the rules of the economic system and, more in detail, of the business context. In other words, it would be the rules and not the nature of the specific objectives pursued that would be the instrument, the levers by which concrete and real economic effects would be produced.

Nonetheless, recently, a general tendency to emphasize ethics and morality within the vast and varied social landscape is increasingly evident. This trend is even more evident in the economic context, where the reputational aspects of the organizations that are part of it have assumed an increasingly growing importance. On the other hand, this has also determined the need to ensure that the pursuit of social, environmental, moral, and ethical aims is achieved not by mere adherence to principles, rules, or regulations but rather by actual behavior directed towards such ambitious non-financial goals (Arjoon, 2005).

Precisely in this direction, corporate social responsibility and sustainability play a key role (Gonzalez-Perez & Leonard, 2013; Chetty et al., 2015), as disclosure, environmental performance, and, in general, social goals are closely connected to the reputation of any type of organization (Surroca et al., 2010; Tang et al., 2012), as a sustainable performance of success leads to a strong and well-valued reputation (Cho et al., 2012).

Indeed, the relationship of mutual dependence between entrepreneurship and the external environment implies that corporate social responsibility can be understood as an important tool for sustainability. In this sense, environmental and social problems do not represent a limitation for organizational performance but, on the contrary, an opportunity for the development of the

company and therefore capable of generating potentially economic value for the company itself (Porter & Kramer, 2006).

For these reasons, the sustainable development has gradually become one of the most discussed topics of our time, although it is necessary to highlight very different interpretations also on the correct meaning of the term “sustainability” applied to entrepreneurial activity.

For example, it is absolutely common to discuss problems related to the depletion of ozone in the atmosphere, the consequences deriving from increasingly anomalous climate changes with respect to seasonal variations, the progressive destruction of biodiversity, and many other issues that clearly demonstrate the absolutely negative potential for the future survival of the human species. In this respect, many authors have begun to argue that, unlike what is currently possible to imagine, entrepreneurial action has all the tools potentially able to ensure the preservation of natural ecosystems, significantly limiting the negative effects produced so far (e.g., Cohen & Winn, 2007; Dean & McMullen, 2007; Shepherd & Patzelt, 2011).

However, alongside the typical environmental problems, it is necessary to highlight that ethical and moral trends mentioned above are further confirmed in numerous and various social objectives that entrepreneurial action often has to face.

In this sense, it is also possible to argue that entrepreneurial action can support communities. Some authors (Peredo & Chrisman, 2006), for example, have theorized the concept of community-based enterprise, which can be defined as a social organization or process in which the community acts both as an entrepreneur and as a company to pursue economic, social, individual, and group objectives of a community: in other words, it pursues sustainable benefits in the short and long term which represent, in essence, the common good and which, mainly, allows us to express two very important logical points.

First, last example is particularly useful for demonstrating that economic profit is a fundamental and necessary element, but not sufficient for the correct and complete definition of

entrepreneurship (Venkataraman, 2019), since the concept of enterprise postulates a plurality of aims and objectives attributable (Peredo & McLean, 2006) and which can be, as previously specified, of an economic and social nature.

Second, this last clarification is very important because the careful reading of what has just been highlighted allows us to identify a common conceptual element which, in fact, also allows us to overcome the same distinction between economic and social objectives. Indeed, it is necessary to start from the fact that the scientific literature shows that there is no absolute consensus on the definition of “entrepreneur” and, considering the latter concept closely connected to the activity of “entrepreneurship”, on what he does in his “entrepreneurial” role (Peredo & McLean, 2006; Venkataraman, 2019).

The two aforementioned premises, therefore, make it possible to support the thesis that allows the recognition of the true commonplace of the conceptual figure of entrepreneurship and, for what has been explained above, of the entrepreneur: the real qualifying element would be the ability to create a significantly greater value, more than the traditional elements recognized in the past (profit, risk, uncertainty, creativity, etc.). The essential point, however, is that the elements deriving from the classical theories of entrepreneurship (Say, 1847; Schumpeter, 1974) are not alternative to the concept of value creation (Moore, 1995; Bozeman, 2007; Esposito & Ricci, 2015; Pavone et al., 2023) but rather the analytical species of it which would represent its genus.

Moreover, Say (1847) wrote that the entrepreneur requires such a combination of “moral” qualities of judgment, perseverance, and knowledge of the world, as well as of business.

Sustainable Entrepreneurship Definitions

Since profit is a fuzzy and multiform concept, it cannot be assumed as a possible absolute indicator of the capacity to create value of any type of economic organization. In this sense, some

authors highlight that although the economic profit of a company can be considered a reasonably useful indicator for estimating the ability to create value, however, it is also argued that the consideration of the social nature of economic activity limits enormously this indicative capacity because, in particular, profit should not be seen as the only absolute and indisputable measure of the ability to create value (Civitillo, 2021), also depending on the fact that it is not always able to always measure customer satisfaction. In this way, some studies show that a broader indication of the virtuous capacities of entrepreneurial activity could be the social impact (Dees, 2001) precisely because the indicators of financial performance would, in many cases, be partial and limiting (Moore, 2000; Ricci & Civitillo, 2018).

Taking inspiration from the reflections set out above, we can emphasize the following key-points about the modern concept of entrepreneurial activity:

- It goes beyond the consideration of profit or, more generally, of financial wealth as an element that is both necessary and sufficient for its exhaustive definition.
- It is built on the growing awareness that, on the contrary, elements typical of both the economic function and the social function of entrepreneurial activity are intertwined.
- Even if it is not possible to highlight a clear prevalence of one over the other, the social function is acquiring, in more recent times, an increasing importance, also due to some current trends relating to the world economy (e.g., Agenda 2030 and SDGs-Sustainable Development Goals).

Sustainable entrepreneurship can be defined as an entrepreneurial action in which the production and exchange of goods and services represents an intermediate, or instrumental, goal in achievement different aims, both economic and non-economic. For economic purposes, profit, income, wealth, assets, and any other element susceptible to an evaluation and an economic or monetary expression are meant; for non-economic purposes, we mean all the objectives that can be generated by

the entrepreneurial function that are not immediately and directly subject to an economic and monetary evaluation and expression: the well-being of the community, life expectancy, social education, equity, equal opportunity, preservation of nature and natural ecosystem, etc.

The balance between economic and non-economic purposes can be ideally represented by a spectrum in which:

- At one extreme, the entrepreneurial processes are located that exclusively pursue the economic purposes (e.g., enterprises).
- To another extreme, the business activities are placed that try to achieve only non-economic purposes (e.g., nonprofit organizations).
- Within the continuum, it is possible to identify countless combinations, in which the mix between economic and non-economic ends can be constructed in various ways, depending on the decisions of the entrepreneurship itself.

However, it is essential to specify that not all the productive combinations that can be placed within the described continuum are necessarily qualified as sustainable entrepreneurship: in fact, the conceptual subdivision between exclusive economic purposes and non-economic objectives is only ideal. Any entrepreneurial activity, even when it can be placed in one of the two abovementioned external points, contains the aims of both categories and, therefore, any entrepreneurial function can basically be placed within the spectrum.

Sustainable entrepreneurship, on the other hand, is the entrepreneurial typology in which the concept of “gain” disregards the “economic” vs. “non-economic” bipartition tradition, to assume an autonomous space in which the focus on non-economic aspects does not compromise the achievement of purely economic objectives. In sustainable entrepreneurship, the non-economic objectives are not considered as simple complements to those of an economic nature: it could be said that this type of entrepreneurship does not postulate a two-dimensional geometric space to be filled through a variable combination of the two types of objectives previously mentioned. On the contrary, sustainable entrepreneurship theorizes a multifaceted

and three-dimensional concept of entrepreneurial space, which is interactive and dynamic, and in which the two ideal elements of which it is composed, economic and non-economic objectives, are not mutually exclusive but, on the contrary, can be fed to each other, generating potential so-called win-win situations.

Summary

Nowadays, the role of the entrepreneur and business organizations in modern economic systems may be a particularly debated issue. It must necessarily be recognized that entrepreneurship presents:

- An economic function, related to the ability to create wealth or profit.
- A social function, related to the achievement of non-financial purposes.

Sustainable entrepreneurship can be defined as an entrepreneurial action in which the production and exchange of goods and services represents an intermediate, or instrumental, goal for the achievement of different ultimate goals that are both economic and non-economic.

The balance between economic and non-economic purposes can be ideally represented by a spectrum in which:

- At one extreme, the entrepreneurial processes that exclusively pursue the economic purposes (e.g. enterprises) are located.
- To another extreme, are placed the business activities that try to achieve only non-economic purposes (e.g. non-profit organizations).
- Within the continuum it is possible to identify countless combinations, in which the mix between economic and non-economic ends can be constructed in various ways, depending on the decisions of the entrepreneurship itself.

In sustainable entrepreneurship the concept of “gain” disregards the “economic” vs. “non-economic” bipartition tradition, to assume an autonomous space in which the focus on non-economic

aspects does not compromise the achievement of purely economic objectives.

Definition

Environmental and ethics is a subfield of applied philosophy that examines the theoretical underpinnings of environmental values and more practical concerns, including societal attitudes, behaviours, and policies that aim to preserve biodiversity and ecosystems

Introduction to Environment and Ethics

Understanding the environment takes a wide variety of knowledge because it is such a broad and nebulous concept. Ethics is concerned with the values that direct people's actions. The philosophical field of environment and ethics, sometimes known as environmental ethics, examines the moral and ethical link between humans and the environment. It examines the moral bond between people and the planet, animals, and plants. In the 1970s, the science of protecting the environment was recognized as a legitimate academic field. Specialists tried to understand how business industries, technology, and the expanding worldwide population have an environmental impact. Ethics is the study of the rules that govern how people behave. Environmental ethics, with its internal conflicts and disagreements, can shed important light on international environmental politics. It covers the right and wrong things to do concerning many issues, such as environmental concerns. What is the right or incorrect activity concerning the environment, which is the goal of environmental ethics? Freedman (2018) identifies the tenets that best explain and outline the ethical interconnection of the environment with individuals. This concept emerged from the realization that environmental challenges as they are understood in the world require a fundamental cognitive foundation. Therefore, environmental ethics can promote scientific heterogeneity in global environmental politics by interacting with the philosophical background of the metanarratives that influence our conceptions of the human relationship and dependency on nature. Early environmental ethics focused on endowing nature with intrinsic value in addition to the operational one that had predominated for several centuries prior. These new ethics needed nature's intrinsic value as its basis to broaden ethics to other living things. Discussions over what would constitute the value-granting characteristic-tying humans and non-humans became exceedingly complicated and challenging (Light 2002; ICFE 2021). An ongoing goal of environmental ethics has been to encourage ways of living that improve a healthy, balanced relationship with nature. The idea and

basis of the environment are closely related to the development of human civilization on earth.

Environmental health is equally important to physical well-being (Macassa 2021). According to religious ethics, love, affection for creation, and justice are essential components (Tarcísio 2018). This situation encompasses Judaism, Islam, and Christianity (Mawil 2011; Hassan 2020). Because of these ideals, numerous legal challenges have also been created. It tries to bring about world peace. This concept was acknowledged in Article 17 of the Universal Declaration of Bioethics, adopted in 2005 at the UNESCO General Conference. According to international environmental law, people should coexist peacefully with the natural world. Global humanitarian organizations and organizations have adopted the notion of environmental ethics. The advancement of environmental ethics, environmental rights, and environmental justice is a significant issue for Friends of the Earth International. Environmental ethics must assess the degrees of value placed on beings other than humans before it can be said to remain a concern of humankind (Kopnina et al. 2018).

The Environmental and Ethical Importance

Applying ethics to the environment is necessary for environmental development, just as it is for business, medicine, engineering, law, and technology. It updates conventional notions of what is morally essential to consider living things like plants, animals, endangered species, ecosystems, and occasionally even the entire planet (Baker and Michael Richardson 1999; Palmer et al. 2014). This idea is significant for at least three connected reasons. To reach the goal of a green economy, global climate governance first looks to construct norms, regulations, and institutions to regulate conduct. To reorganize our connection to the planet and its inhabitants, we must be involved with sustainability technology's ethical part (Kothari 1994; Kibert et al. 2012).

Moreover, the need for fundamental rethinking is essential for humans to exist in nature, moving

beyond concepts of dualism and separation, as well as a radical rejection of the notion that humans are the only source of value, including all other living things and inanimate objects. Third, human behavior is seen by global environmental politics as a significant contributor to the issue. Thus, we must also look at the philosophical environment and the values that form it. When Routley (1973) asked if we needed a new sort of ethics, he made the first historical reference to environmental ethics. He created "the last man's" philosophical exercise. According to Liobikiene and Poškus (2019), the complexity of environmental protection acknowledges the root causes of environmental concerns highlighted towards the humanistic legacy for isolation of meta-conceptual previously discussed, strengthened by the influence of technological advancements and by a smug attitude toward nature. Technology has permeated every aspect of our life to the point where we regard them as incredibly important to survival (Valera 2020). A circle of responsibility for the natural world is added by environmental ethics, starting with domesticated animals as pets or cattle, followed by those utilized in zoos or for medical research. In addition, there are obligations toward wild creatures. If one hunts, do it compassionately (Erica and Michael 2021).

Types of Environmental Ethics

Environmental protection has been dominated by discussions of several ways to root the inherent value of nature for centuries, giving rise to several types, including animal rights, fundamental ecologism, property ethics, biocentrism, and feminist theory.

Animal Liberation: One of the most well-known representatives of all these pro systems of thinking is Peter Singer (1975). He gave a critical speech that helped launch the fight for animal liberation. Since Singer upholds the concept of equal representation of interests for all people, including nonhuman animals, there is no moral basis for exploiting animals. The equality

principle also enables Singer to reject and denounce inhuman treatment. Singer claims that the rationale for torturing, killing, and ignoring animals' existence comes from speciesism.

Land ethics: This was influenced by Aldo Leopold's writings (1887–1948). He suggests that we should value land philosophically, expecting the fundamental value of nature rather than economically. The works of Callicott (1999) aimed to create a conceptual part to land tenets that ordered more people than the researcher Leopold did. This researcher calls for a metaphysical transformation from an individual while advancing the notion that humans and nature, taken as a whole, are one new being.

Deep ecology is a third trend in environmental ethics and was put forth by Arne Naess (1973), who distinguished between superficial ecology and fundamental ecology, the latter defined by seven normative principles that offer a single implementation for ecosophical systems. Fundamental ecology differs from other forms of ecology in that it focuses on ontology, the consciousness of individual states, and tries to expand it further.

Ecofeminism: Ecofeminism is a fourth non-essential trend. It falls into two categories: firstly, acknowledging gender differences while also trying to value female traits that are underrated in Modern nations; and secondly, advocating the rejection of both masculinity and femininity in favor of creating a new culture. This term is known as the difference and the deconstructive models, according to Dobson (1995). The principal proponent of the deconstructive concept is Val Plumwood (1993, 2002), who contends that dualisms obstruct genuine advancements in ecofeminism. Male and females should oppose the dualized perspective on human identity and create a new culture that indeed acknowledges uniqueness as concurrent with, not apart from, nature (Plumwood 1993; Douglas and Michael 2017). It encourages the notion that transforming source to thinking is required in a non-patriarchal setting and entails rethinking knowledge, reality, and ethics.

Principles of Environment and Ethics

Using ethical principles as criteria or benchmarks allows us to assess our behavior. They are moral standards. Justice and sustainability, sufficiency and compassion, and solidarity and participation are fundamental pairs of concepts. They have roots in many civilizations, including Greek philosophy, religious doctrine, and the human condition contemplation.

Principle of justice: The conventional rule of law emphasizes that everyone has the right to be treated unless there is a valid reason not to. Although it can be undoubtedly pertinent to all ethical areas of the law, this principle applies to many problems. It is concerned with the unfairness of higher pollution and the inequalities in accessibility to the natural resource (clean food, air, and water), which often characterize lower-income regions rather than affluent suburbs. Justice is extended into the future via sustainability. The ethical concept of fairness is in play because it supports the requirement to balance the demands of those who live presently (both wealthy and less privileged) with the requirements of future generations. Therefore, environmental rules broadened the idea of fundamental justice that must include the future generation (Keith 2009).

Principle Sufficiency and Compassion

According to the sufficiency principle, all living things must have access to enough resources to survive and thrive. Intolerance of mismanagement of resources intended to be sufficient for people. Maintaining the standard of sufficiency places obligations on both individuals and human groups to ensure that everyone has access to the resources they require to keep a life of self-respect. These demands include sharing, living more simply, and exercising creativity. The idea of ethical significance denotes that something deserves moral care. This feeling is closely related to the ethical norm for sufficiency. It thus suggests that we consider what others need from us. It serves as the foundation for empathy. This principle may contrast with

the idea that there are not enough resources on earth to meet everyone's needs, particularly in some people's opinions. According to environmental ethics, humans must act to meet the needs of all living things, including other creatures, vegetation, and the environment.

Participation and Solidarity

The concept of solidarity challenges us to consider how we relate with each other. In a world where the economy is becoming more globalized, we are a part of a big, interconnected economic society where people on the other side of the globe provide our needs with goods and services. To be in a position of solidarity, we must consider this type of larger community and act in a way that shows concern for the welfare of others. The need for solidarity directs our attention to the concept of inclusion and enables those who may be affected by environmental policies to influence these same policies. Transparency, or the availability of the same information to everyone, is a prerequisite for genuine involvement. Environmental ethics emphasizes the need to consider people's moral character and behavior more than conventional environmental protection, which is primarily concerned with the intrinsic nature. Sandler (2005) states that human develop laws, advance policies, and behave toward nature according to their personality traits, attitudes, habits, and inclinations. Identifying environmental virtues and the character-based role that individuals play in applied protection is possible. Morality considers the growing significance of welfare in only modernization dialogues, connecting with the position of rightness in personal growth, attitudes, and ways of life, and integrating a feeling of instilling human attributes that improve a balanced and cohesive connection and interaction with the environment. It emphasizes protecting coming generations and the significance of virtue morality discourse in policy measures taken during an environmental setback. The conventional rule of justice states that

humans should be treated equally irrespective of their personality, unless there is a compelling cause to do otherwise.

Environment and Ethics in Theory and Practical

Environmental ethics, in theory, and practice, is about having the correct values and obligations for the natural environment. The study of environmental ethics has focused on finding and understanding the principles that have influenced how people interact with nature and the foundations of various interactions, such as reliance and connection. Direct or indirect connections exist between environmental ethics and effective governance, addressing these societal wellbeing challenges (Noor 2011). Environmental ethics is a moral framework regulating how people think, act, and behave when engaging with the environment. Internalizing environmental ethics helps people think morally, so they may consider social, economic, and environmental factors when implementing sustainable development (Heruyono et al. 2021). Environmental sustainability has ethical implications in addition to academic and practical ones. It can be incorporated into existing social work ethical statements that fully extend the ideals of justice in the natural environment field (Bowles et al. 2018). Environmental ethics are crucial and understanding their significance can help the environment and people.

Environment, Ethics, and Globalization

Environmental ethics is essential for sustainable development and protecting the environment in the present era, which dates to the earliest ancient civilizations (Noor 2011). Due to its consequences in the development discourse, it is already a global problem. However, most people in both developed and undeveloped nations are unaware of its significance. It is simple for everyone to set up their obligations and duties

effectively, which could result in sustainable growth while considering environmental ethics for our future generations to live in peace and happiness on our planet (Noor 2011). In the present world, the concept of the environment is entirely different. Today's environmental understanding is primarily micro-based. The environment and globalization policy openly acknowledge the importance of the natural environment to human survival (Bowles et al. 2018). Environmental philosophy and ethics, however, continue to be under-represented in most world environmentalism discourses and literature, despite the clear inadequacies of restricted disciplinary approaches. These current approaches are linked to socioeconomic, geopolitical, and ethical issues primarily represented by environmental pragmatism and virtue ethics. It educates us to lead healthy lives and to be supportive of human progress and the environment. This attribute is primarily found in international human rights law regarding internationally recognized law. Incorporating the necessity for environmental protection into the community is to achieve sustainable development. It has been a major undertaking for contemporary time, including the UN organization, its competent authorities, and other global and regional bodies. The effects of globalization on contemporary society are adverse because we lack a broad perspective or style of thinking. Some nations, including the USA, India, Sri Lanka, the UK, Bangladesh, the EU, and Pakistan, are concerned about the environment's devastation and contamination. They are involved in the development and environmental conservation problems. To achieve global sustainability, we must address sustainable practices, ethical planning, management challenges, and ethical tourism (Nicholas and Thapa 2010). In addition, most significant law schools, like Macquarie Law School, the Environmental Law Centre at the National University of Singapore (NUS), and the Pace Law School, have played crucial roles in addressing environmental and ethical issues both domestically and internationally. The worldwide concept of social work and any future Declaration

of Ethical Principles must incorporate sustainable development and the preservation of the environment (Bowles et al. 2018).

The Relationship Between Environmental Ethics and the Environmental Sciences

Environmental and ethical considerations are linked to development and a sustainable environment, respectively (Patra 2014). Various scientists from various professions and using various references have described domesticated animals as the entirety of the surrounding universe, including plants (Noor 2011). Environmental ethics defines man's moral and ethical responsibility to the environment. It considers the moral interrelationship between humans and the natural world and the kind of environmental decisions that individuals must make. Environmental ethics provides moral justification for societal policies that strive to preserve the environment and reverse environmental deterioration (Barman 2017). Science and technology have contributed to the modern era, and civilization now relies on technological development. Information technology and technology, in general, have significant adverse effects on the environment (Thomas 2006). According to Light (2002), environmental ethicists should concentrate on finding the best ways to assist the environmental community in reasonable conscientious justifications for favoring the initiatives upon whom our opinions currently generally coincide. Callicott (2018) asserted that humanistic environmental ethics should be important to human beings. Since this upcoming environmental issue is detrimental, the author continues, it is fundamentally a matter of global warming ethics. He acknowledged the necessity for an upgrade of environmental ethics.

Multidisciplinary research is involved in environmental ethics. Ability in biology, physics, law, economics, psychology, sociology, and philosophy is incorporated. Environmental protection concerns the preservation of animals, freshwater

use, fresh air, and mineral production and can be broadly divided into descriptive and normative categories (Envethics 2005). Environmental ethics studies how morally responsible humans should be toward the environment. In the 1970s, an area of philosophy called environmental philosophy was formed. The Population Bomb by Paul Ehrlich published in 1968, and Silent Spring by Rachel Carson published in 1962 both described how the widespread use of synthetic chemicals posed a severe threat to public health, being the cause of the extinction of wildlife. Both books were influential and released around the same time (ISE 2006).

We must adhere to the morals outlined in the holy scriptures such as Quran, Bible, gospel, and others because this topic has been treated in these religions in several ways (Mollah and Dastagir 2010; Ibrahim 1983; Alwazna 2016). Environmental ethics merely seeks to address the issues of how people ought to interact with their environment without having any special international environmental codes (Barman 2017). All human and natural qualities are a prerequisite for environmental ethics. It is necessary for a sustainable environment and future (Simon 2010).

According to some experts, the continents once broke apart, which is why they are progressively drifting away. It means that the movement disturbs the earth's surface. People are the only ones responsible for these issues and the injustice done to the environment. Science and technology have contributed to the modern era, and civilization now relies on technology. Information technology and technology, in general, have significant adverse effects on the environment (Mahdavi and Sojoodi 2021). Environmental ethics and rights are interconnected. Every living thing on earth has rights, and this includes the environment. It discusses the 1998 Aarhus Convention. It means having entrance to unpolluted, uncontaminated, and clean environments necessarily needed by everyone to survive. Additionally, they cover extensively the ecologically focused values, such as the opportunity to appreciate an unaltered landscape or the need for certain

insects to exist. Most activities rely on technologies, including the net, computers, and related tools that promote environmental research and sustainability.

Summary

The importance of environmental ethics in present-day society is indispensable. The value of environmental ethics in today's culture cannot be overstated. Our ability to live on this planet, our home depends on our adherence to current laws, regulations, and environmental ethics. It addresses issues such as environmental protection, ethical instruction, ancient traditions, and nature stewardship that are essential to humankind's continued sustainability on our planet. All ethics, including environmental ethics, aim to value life appropriately. The complete environmental ethic requires the best naturalistic and humanistic justifications for preserving ecosystems. We might be able to solve 90% of our problems or more if we cared more about how ethical issues are applied to all situations, including the environment. Environmental ethics and its methods can be beneficial in running our lives efficiently and creating a balance between humans and other creatures in the environment.

Introduction

Climate change is one of the global issues where individuals, nongovernmental organizations,

governments, and corporations make coalitions to face a common concern. Nowadays, public opinion pays attention to those firms that do not show defiance of environmental and societal issues and further topics like transparency, business ethics, females' employment rates and wages, etc. that could be covered by the term corporate governance. Thus, modern consumers and investors consider firms with environmental, social, and corporate governance criteria. Therefore, the term ESG criteria has been created. In brief, the ESG criteria include issues like pollution, gas emissions, waste management, climate change, biodiversity loss, ozone depletion, renewable energy sources, etc. regarding the environmental field. The social field includes topics like human well-being, safe and good working conditions, local communities, etc., and governance field is about business code of conduct, wages discrepancies, gender diversity, equal opportunities, etc. (Sciarelli et al., 2021: 42).

To achieve long-term sustainable growth, you need the right balance among system, people, and culture...

Jack Ma, Cofounder and executive chairman of the Alibaba Group (*Setting the New Agenda for CFOs: Understanding the Role of Intangibles in Value Creation*, , 2021)

ESG Advantages for Companies

It is acceptable in general that companies with ESG action enjoy recognition by consumers and investors. Two global researches by McKinsey (2009 & 2019) conclude that most of managers agree that ESG activities enhance a company's value (McKinsey & Company, 2020). There is evidence that ESG firms are characterized by better financial performance, surplus value for their shareholders, and less volatility during recession periods like the global crisis of 2007–2009 and the current crisis with the pandemic of COVID-19 (Albuquerque et al., 2020).

Many researchers support that ESG programs serve a product differentiation strategy for a firm. Environmentally and socially responsible consumers become more loyal because they

appreciate this kind of orientation of the company. There is evidence that socially responsible consumers operate as significant factors for firms' transformation, CSR policy, and risk profile (Albuquerque et al., 2019). Furthermore, the firm earns a lower price-elasticity of demand for its products or services. Thus, higher profit margins could be achieved, and better financial performance could be expected along with better resistance during depression periods (Albuquerque et al., 2019).

ESG stock shares are more resilient to a downturn of the stock market. The investors who are environmentally and socially responsible are more reluctant to sell off their shares, and this fact keeps relatively stable the stock market prices in comparison with competition (Heinkel et al., 2001). Stocks with ESG characteristics and strong advertising policy managed to perform successfully during the first year of the pandemic. Furthermore, companies which managed to protect their workforce and apply sustainable supply chain principles maintained higher returns than competition in the US stock market (Albuquerque et al., 2020). However, and this concerns both the depression of 2007–2009 and the current pandemic, it is complicated for researchers to discriminate whether the good performance of ESG firms is due to their ESG strategy or it is the bond of trust between them and the market (Albuquerque et al., 2020).

Corporate governance is crucial to the continuing operation of any firm, and it is not limited to serve shareholders' welfare. High level of corporate governance targets to transform companies to ESG highly ranked companies by deterring frauds and scandals that could destroy firm's reputation (Kantabutra & Saratun, 2013). Being socially responsible or enhancing your ESG footprint increases the value of a company either by raising earnings and cashflows or by limiting the discount rates. Even though the influence of ESG on profitability is poor, firms that pay attention to ESG criteria are less risky and it is not probable to expose themselves to reputational and catastrophic risks regarding environmental or societal issues (Cornell & Damodaran, 2020).

Of course, there is a totally opposite opinion stating that pollution should be cleaned up by society or state. There is the famous statement attributed to Friedman, even a lot of business people had applied this concept much earlier than his statement, that the unique target of a company is to create wealth for its shareholders (Friedman, 1970). ESG programs are considered just a field of conflict between managers and owners, and a smart way for managers to confuse deliberately shareholders gaining more benefits for them (Albuquerque et al., 2020).

Critical element of any successful ESG or CSR policy is communication. It is true that there is no agreement among all researchers regarding the positive impact of ESG activities to a firm's overall performance. However, there is clearly a positive relationship between a well-communicated public ESG program and a firm's value (Servaes & Tamayo, 2013).

ESG and SRI

Big international scandals with environmental and financial impact from the last decade of the twentieth century and the first two decades of the twenty-first century like Exxon Valdez, Bhopal, Nike, Parmalat, Volkswagen, etc. accelerate the development of environmental and social awareness of firms and funding agencies. The same applies for the big depression of 2007–2009 which has caused a big lack of trust between business world and people. Thus, fund managers have started assessing their investment strategies using ESG criteria expanding the horizons of their investments reducing the risks and creating new opportunities for their investments (Sciarelli et al., 2021: 41). As a result, investors have decided to align their investment decisions with their personal values and sensitivities and they have leveraged firms to voluntarily limit their negative footprint on society and environment (Vanwalleghem, 2017).

SRI is a modern kind of investment that combines the classical financial characteristics with the integration of environmental, social, and

corporate governance criteria (Michelson et al., 2004). From a strategic point of view, this signals the incorporation of business ethics into traditional investment decision-making. From the operational point of view, this new kind of funding serves the transition to sustainable development (Sciarelli et al., 2021: 41). Currently, banks and international funding agencies are attracted by SRI and eschew to invest in firms with high ESG risk like polluting firms (for example, oil exploration and production companies). As the percentage of green investors is getting higher year by year worldwide, companies with lack of ESG strategy will have problem to raise funding and will face an increased cost of capital. On parallel, there is a significant percentage of consumers with increasing trend that care about ESG and boycott socially irresponsible suppliers. In this case, top managers of companies are going to be engaged in the operational ethical dilemma where they have to decide whether they have to support a possible reformation of their activities toward a more sustainable model or they should not invest in CSR programs for the favor of other usually short-term goals (Panagiotopoulos, 2020). However, it is rare for a big international organization not to have a CSR policy since the popularity of CSR nowadays implies its existence (independently of the real level of its adoption in corporate activities) even bypassing the research that may require to reason it (Albuquerque et al., 2019).

SRI funds have increased their share in global market. The Social Investment Forum in the USA and the Social Investment Organization in Canada are examples of such organizations that count already more than twenty years in ESG investments. It is not clear whether such organizations eschew investments in low-ranked ESG firms because they prefer to extract satisfaction from their noninvolvement in risky activities or they leverage such firms to rethink their ESG transformation (Heinkel et al., 2001). SR or ethical or sustainable investments are taking increasing share of international funds in comparison with the recent past. This is caused by the increased interest for corporate social responsibility by

consumers and the developed social awareness by organizations, institutions, and funding agencies (Sciarelli et al., 2021: 39–41).

ESG and CSR

The ESG criteria consist another way to talk about CSR. CSR is a term that usually comes for corporations' side since it is their creation, expresses how they realize their corporate citizenship, and embraces the environment, local communities, and employees. On the contrary, ESG is a term that comes outside of companies' environment, mainly from institutions like banks and consulting firms when they want to refer to sustainability and CSR issues of business world. ESG has come up in the United Nations Principles of Responsible Investment Report, and its use by banks and consultants consists to collect further financial and nonfinancial information about the environment, society, and corporate governance issues in order to have a more spherical picture of a company's position in the market and to better assess any possible risk or chance prior to any investment (United Nations & Mercer, 2007).

Both concepts have the same meaning and target to mitigate the negative social, environmental, and economical impact that comes from a company's actions and furthermore, to increase the positive social, environmental, and economical impact of a company's operation. The recognition and the involvement of stakeholders' interests into the decision-making process of a company is a major way for the fulfillment of these goals. Examining ESG criteria through the consideration of CSR policy of a firm as part of its intangible assets unfolds various dimensions of intangible corporate value, facilitates banks to use knowledge about intangibles to reason lending decisions, and provides new management control perspectives and investors' investigations and decision-making (Setting the New Agenda for CFOs: Understanding the Role of Intangibles in Value Creation, 2021).

A corporation's endeavors inside the frame of CSR policy could be described by the term

Corporate Social Performance (CSP) meaning the conjugation of efficiency and effectiveness to apply their ESG plans. As ESG and CSR are getting more popular between companies, consumers, researchers, and market analysts, focus on CSP and its impact on market value comes into the spotlight. Several researchers (Oikonomou et al. 2012; Mc Williams and Siegel 2001) support that a successful CSP enhances market value because it reduces costs and idiosyncratic risk. Other researchers think that the investments in ESG consist waste of money, time, and workforce (Groening and Kanuri, 2013). However, the interaction between ESG and CSR with a firm's financial performance and market value cannot be defined so easily. The quality of CSP and the efficiency of communication of CSR policy to the market and the society are critical factors that could have big fluctuation; thus, the answer to such questions cannot be binary. Most studies have tried to correlate an intense CSP with benefits back to the firms (Mackey et al., 2007), and thus the research is limited in cases where there is a weak CSP and how this affects a firm's value. Despite the conflict regarding the positive or negative influence of CSR and ESG to the financial position of a firm, unequivocally everyone agrees that the consideration and perusal of ESG factors offers an all-around picture of a firm about its position inside the multiple environments where it is activated, local market, international markets, etc. It is therefore true that the knowledge about CSR or ESG parameters offers safety and a more efficient risk management to firms, institutions, and consultants (Bassen & Kovacs, 2008).

ESG Reporting

There have been a lot of efforts toward the direction of a comprehensive reporting of ESG policy of a company. There is need for international standards that could offer guidance to firms and institutions regarding the reporting of this non-financial information which could be critical for the viability of an organization. The United

Nation's Global Reporting Initiative (GRI) is the most popular reporting standards regarding CSR/ESG policies. There is the World Intellectual Capital Initiative (WICI) which consists an international reporting network that assists companies and their stakeholders to put on paper ESG issues and express their importance through measurements with Key Performance Indicators (KPIs). WIPI concentrates international organizations like OECD, the Enhanced Business Reporting Consortium (EBRC) and the EFFAS Commission on Intellectual Capital (EFFAS CIC), Japanese Ministry of Economy, Trade and Industry (METI), Waseda University, and University of Ferrara, European Financial Analysts, Commission of Intellectual Capital, European Commission (observer), European Investment Bank (EIB), World Intellectual Property Organization (WIPO) (observer), Brazilian Development Bank (BNDES), and Society for Knowledge Economics in Australia (SKE) (Bassen & Kovacs, 2008).

The traditional sources for business are tangible things like machinery, real estate property, vehicles, and other technological equipment like IT infrastructure, etc. Modern corporations tend to spend an increasing amount of money to intangible assets like public relations, know-how, branding, research and development, and CSR. These nonphysical resources either separately than the rest or in combination with other tangible or intangible resources cause a positive or negative impact to firm's total value. Materiality comes through the conjunction between financial and ESG considerations (Setting the New Agenda for CFOs: Understanding the Role of Intangibles in Value Creation, 2021).

There is dispute regarding the value of considering ESG criteria. There are researchers and businesspeople who treat them as being risk factors which have influence on investment performance and, on the other hand, had some others believe that they are just social issues. Recently, the evidence of materiality concerning ESG parameters is spread worldwide, and an increasing number of researches support that (United Nations & Mercer, 2007).

The publication of the Principles for Responsible Investment (PRI) suggested a standard for

the incorporation of ESG parameters into the investment process. The PRI consists a global guide for SRI, and ESG as a term has been embodied in the modern financial vocabulary having as main target to make ESG part of every investment analysis and decision-making process (United Nations & Mercer, 2007).

The discussion around ESG and CSR includes issues like the potential return to the companies that have socially and environmentally responsible attitude, and their ranking. However, an ESG ranking seems to be complicated since it contains a lot of parameters comprised in three different groups environment, society, and governance. A report had identified 70 firms which used to provide ESG ratings up to 2019 excluding organizations like investment banks, state institutions, etc. that examine firms based on their ESG criteria and provide relevant ranking. Including any kind of ESG ranking, Fish et al. detected more than 600 ESG ratings in 2018. All these ranking systems are not based on the same philosophy since they may contain different parameters, and even regarding the same parameters, they may count them with a different way. Each ESG ranking system has a different prioritization of a multitude of parameters based on the beliefs of its creators about what really matters. However, we could claim that there is a common pool with topics and from there several indicators may come up. Bloomberg uses an ESG system with a hundred twenty ESG criteria. The main topics with which the majority of criteria are related refer to climate change, biodiversity, carbon emissions, energy management, waste management, discriminations at workplace, diversity, human rights, corruption, etc. (Cornell & Damodaran, 2020).

European Union and ESG

There were specifically in Europe 12 trillion US dollars that were going to be directed to ESG investments in accordance with Bloomberg report on February 8, 2019. Lawrence Fink who is the CEO of Blackrock said that it is impossible for a firm to discriminate its ESG responsibilities from

its efforts for growth and that its development target passes through a combination of balance with stakeholders' interests (Cornell & Damodaran, 2020).

The European Green Deal is Europe's common plan for sustainable development. It has as target the high living standards of European citizens concerning their health and natural conditions, a Europe climate-neutral by 2050, and the protection, preservation, and development of EU's natural capital and biodiversity. An economy that works for people implies a just transition that produces working positions for all. Thus, the European economic system must become more sustainable. This demands a strong common European financial legislation and a clear guide for this economic transformation. This long-term goal must take into consideration the financial recovery from the COVID-19 pandemic and keep stable its orientation for a sustainable European economy (EU Taxonomy, Corporate Sustainability Reporting, Sustainability Preferences and Fiduciary Duties: Directing Finance towards the European Green Deal, 2021). Regulation (EU) 2020/852 outlines a framework for sustainable investments (the EU Taxonomy Regulation) that entered into force on 12 July 2020. Through this regulation, technical screening criteria are provided for examining whether a financial activity could be environmentally responsible. These parameters assist firms, banks, investors, and consultants to discriminate which policies, strategies, and financial activities could be characterized as environmentally responsible (EU Taxonomy, Corporate Sustainability Reporting, Sustainability Preferences and Fiduciary Duties: Directing Finance towards the European Green Deal, 2021).

There are stakeholders that worry whether the scheduled actions by a firm could satisfy ESG criteria, for example, by using the EU Taxonomy Climate Delegated Act because a possible failure may arise difficulties for fundraising for them. However, it should be highlighted that whether a firm has a policy that could be characterized as ESG responsible based on their compliance with EU Taxonomy, this does not exclude it from

raising capital and this does not mean that it is ESG irresponsible. The EU Taxonomy is a transparency tool that calls corporations and other economic factors to disclosure activities related with sustainable economy. Especially the percentage of the activities that comply with Taxonomy could operate as a comparative criterion for the assessment of corporate programs. The EU Taxonomy considers corporate activities as environmentally responsible whether they have a substantial rather than marginal impact especially to EU environmental objectives. The EU Taxonomy has defined the standards for substantial participation and absence of critical harm, having as reference the targets described by the European Green Deal. Other tools like the EU Ecolabel for retailing financial products and the EU Green Bond Standard are expected in the next years to further support the endeavors for a sustainable European economy (EU Taxonomy, Corporate Sustainability Reporting, Sustainability Preferences and Fiduciary Duties: Directing Finance towards the European Green Deal, 2021).

Anti- Epilogue: Shareholders Versus Stakeholders

In parallel to increased environmental concern and social focus on ESG issues, a main driver toward sustainability is that there is a big group of industries related to these emerging ESG issues that have a high potential to generate new sources of revenue and profit. Indicatively, this happens with the developing industry around CO₂ extraction, sequestration, and trading, all of which appear poised to grow rapidly over the next 5–10 years with liquidity also building in the CO₂ emission credit market. However, financial history has shown that today's promising new entrants do not necessarily become tomorrow's successful enterprises (United Nations & Mercer, 2007).

Friedman stated in 1962 that “*There is one and only one social responsibility of business—to use its resources and engage in activities designed to increase its profits so long as it*

stays within the rules of the game, which is to say, engages in open and free competition without deception or fraud.” (Friedman, 1962). On the contrary, the announcement from the Business Roundtable in 2019 signed by several famous CEOs mentions that “*Each of our stakeholders is essential. We commit to deliver value to all of them, for the future success of our companies, our communities and our country.*” (Cornell & Damodaran, 2020).

Environment, Tourism, and Sustainability (Ecotourism Management, Environment and Sustainable Tourism)

Nil Sonuç

Faculty of Tourism, İzmir Katip Çelebi University, İzmir, Turkey

Definition and Conceptual Framework

“Only when the last tree has died and the last river been poisoned and the last fish been caught will we realize we cannot eat money”. (Prophetic Cree Proverb)

“On a finite planet, at human carrying capacity, a society driven by selfish individualism has all the potential for sustainability of a collection of angry scorpions in a bottle”. William Rees (Wackernagel and Rees 1996: xi)

Summary

The environmental dimension of the sustainable tourism will be dealt with under this topic by trying to understand environment, tourism and sustainability relationship. Comprised of this framework, the sustainable tourism practices respectful to environment, the most prominent called ecotourism, will be referred. In order to have a good understanding of the given subject, it is essential to be knowledgeable about certain issues related on the one side to tourism which is a very complex industry – of course with sustainability perspective – and on the other to environment which has a quite wide knowledge base for the existence of the world. Main terms related to environment attempted to clarify include biodiversity, ecological footprint, climate change, reduction of carbon emissions, and the like.

Conceived in 1990 by Mathis Wackernagel and William Rees at the University of British Columbia, the “ecological footprint” launched the broader “footprint” movement, including the “carbon footprint,” and is now widely used by

scientists, businesses, governments, individuals, and institutions working to monitor ecological resource use and advance sustainable development ([Global Footprint Network](#)). As underlined by William Rees, the environmental crisis that is present in the world today is beyond being a technical or environmental problem. The problem ingenerates because of the wrong sociocultural and behavioral practices. Cooperation of individuals within society along with proper behaviors must be taken into account toward protection of environment while benefiting from it economically; thus, sustainability perspective is emphasized (Wackernagel and Rees 1996).

Similarly the unwelcome results of over-individualism to meet the individualistic needs without considering any backfiring outputs over the same shared environment are tried to be symbolized in the following proverb given at the beginning of this part. As may be concluded from the Prophetic Cree proverb, if the resources of the world are inattentively overexploited for the sole aim of financial gain, harming the environment or even destroying it until extinction of certain species, then humankind will no more be able to find any resources in the end to continue to survive. Additionally, the money earned in the end will be meaningless; it will not feed the humans.

If tourism is not practiced sustainably, the same risk is valid for the outputs of this highly complex industry. Hence, the management of environment, tourism and sustainability means creating the balance between exploiting the natural and cultural heritage resources for the service of tourism industry and simultaneously protecting them. To be able to realize this aim, certain solutions are created by the perspective of sustainable tourism as exemplified by such participative practices as ecotourism, rural tourism, community tourism, agrotourism, voluntourism, heritage tourism, and so on.

Sustainable Tourism and Environment

Sustainable tourism from the environmental dimension tries to manage with participative systems to keep water, energy, and air clean while

avoiding the risks of environmental loss (the loss of biodiversity and environmental resources) and measures to prevent risks of overcrowding, over-exploitation, or extinction. The “participative system” exhibits the keyword and the way the management function of the sustainable tourism should work. If the focus is not primarily on the profit but on the sociocultural gain, then the locality will earn. And finally there will be a win-win situation for all the parties including the environment. The protection of the natural and cultural resources as well as the well-being of the people living harmoniously with their surroundings will not be a dream but reality. Thus, if the primary aim of the investment projects for the sustainable tourism is the protection and upkeep of resources while sharing the benefits with the guests and the local people, then the aim of gaining touristic socioeconomic value will happen to follow automatically.

That shows what the philosophy of the sustainability is: to live in harmony with the environment, keep biodiversity and natural heritage, and reduce carbon emissions and its effects on global warming and climate change. People and industries leave to the world their footprint in each of their actions while living. If they behave considerately toward the environment, their actions will not harm it. But this is not the case since the second half of the nineteenth century when people began the autonomous production and consumption and thus produce and consume more than they need, harming the world’s resources. Today, the inevitable consequences threatening even the humankind happen to appear such as the global warming and climate change. The people in the world should calculate their actions more stricter and prudent than ever if they wish the species of the world including themselves do not become extinct. Some measurements and precautions exist for the calculation of the steps more carefully such as “ecological footprint.” The ecological footprint is defined as “the only metric that measures how much nature we have and how much nature we use,” and it is noted that “the Footprint helps countries improve sustainability and well-being; local leaders optimize public project investments, individuals understand their

impact on the planet” ([Global Footprint Network](#)). Footprint in this respect is also mentioned as combined by certain other words such as “environmental footprint” and “carbon footprint” ([Safire 2008](#)).

Ecological footprint in the framework of tourism is mentioned by Hunter ([2002](#)) as “Touristic Ecological Footprint” (TEF). In this study, it is concluded that as a result of the production and consumption of all the tourism services such as transportation, accommodation, and food and beverage, there is a need to develop more sophisticated methods of measuring the footprint left by not only the consumer side but also the producer side.

In order to understand the environmentalist discourses, the study of Bäckstrand and Löfbrand ([2006](#)) may be referred. Three basic discourses are mentioned in their study: ecological modernization, green governmentality, and civic environmentalism. Accordingly, “the ecological modernization beginning from the 1980s and with the Brundtland report “Our Common Future” is a discourse of ecological modernization gained ground in Western industrial societies, which challenged the notion that modern civilization is facing ‘limits to growth’ as suggested by the Club of Rome in 1972. The distinct feature of ecological modernization is the compatibility of economic growth and environmental protection, a liberal market order and sustainable development”. By this discourse, forests are considered as “instrument for low-cost climate mitigation and maximized synergies”. “Alongside the market-oriented approach to environmental problem-solving proposed by ecological modernization, a discourse of green governmentality predominates in industrialized societies”. Forests are considered as “sinks and reservoirs of carbon” for this discourse. “The civic environmentalism discourse is associated with the 1992 United Nations Conference on Environment and Development (UNCED) held in Rio de Janeiro, where the language of participation and ‘stakeholding’ entered the global environmental agenda”. By this discourse, forests are considered as “sources of biological diversity, livelihood and cultural values”.

A study going beyond discussing whether the tourism activities are environmentally sustainable or not tries to create reciprocally beneficial connections between tourism and environmentalism by emphasizing “the potential for tourism operators to play a more active role in cultivating an environmental practice that can persist beyond the ecotourist bubble” (Stoddart and Nezhadhossein [2016](#)).

Environmentally Sustainable Tourism Practices

The most strictly environmentally sustainable tourism practices are to be normally realized under the umbrella of ecotourism if a distinction is to be made. However, a confusion and diversion exist both in the academia and in the sector so as to where sustainable tourism borderlines begin and end especially apropos of ecotourism. In the earlier publications such as Weaver ([2001](#)), ecotourism is mentioned as a synonym to sustainable tourism, and even, it is classified as hard or soft in terms of conforming to the criteria of sustainability more or less strictly. On the other hand, in the more recent publications such as Cater et al. ([2015](#)), it is included in the totally sustainable portion of the tourism industry. Ecotourism is defined by The International Ecotourism Society as “Responsible travel to natural areas that conserves the environment, sustains the well-being of the local people, and involves interpretation and education” (TIES [2015](#)). Similarly, a study discussing the ecotourism in Belize prefers three local criteria which are told to be similar with the objectives of sustainable tourism, generation of local economic benefits, financial support for local protected area management, and local support for conservation. Besides, the results of this study prove for the local case studies of ecotourism that, in practice, the criteria of ecotourism or sustainability is only partly met, not fully (Lindberg et al. [1996](#)).

It is not the definitions or appellations that matter; what matters is the behavioral and attitudinal perspectives which create and determine the perception and implications toward a more

sustainable tourism respectful to environment. Here, the behaviors and attitudes may be classified basically into two bodies: individual and organizational. Individual part belongs to the guests and the people that they interact with while they consume the touristic products. This can vary from not picking up a flower, picking up the rubbish, or throwing away the rubbish to the places shown at the destination to preference of bicycle instead of car while wandering at the destination to reduce carbon emissions. The second body belongs to organizational behavior such as investing in sustainable projects not harmful to environment, using filters and necessary equipment for the protection of air and water, preferring renewable and saver systems for energy consumption, etc. Of course, this is not so easy after all the wrong patterns that have been practiced through long years. To change into the correct behavioral patterns toward environment, education has the most essential and central role among all other necessary precautions. Education for all parties involved in tourism carries importance, including guests and staff (TIES). However, the urgency of strong sustainability education especially for the tourism scholars is called by Cotterell et al. (2019) who additionally emphasized that in order to create future industry workers capable of being sustainability leaders, skill development in areas such as reflective thinking (Howlett et al. 2016), systemic thinking, compassion and empathy, and ethical practices (Wals and Blewitt 2010) need to be developed.

For defining the behavioral perspectives and interactions in the framework and decision-making process of the actors involved in sustainable tourism varies from the tourist to the local and central governmental authorities, some related terms are used such as “green tourism, green innovation strategy, green preferences of tourists, and green tourism products”. The benefit of using these terms on the level of the local economic and branding issues are also discussed (He et al. 2018). However, if ecotourism and its neighbor, sustainable tourism, are used purposefully for the sole purpose of branding without respecting and realizing the requirements and principles of ecotourism, then it becomes

“greenwashing” which has a negative value in meaning. Some, but not all, of greenwashing is reported to be as a reason of a lack of understanding the principles of ecotourism (Wood 2002). In a paper discussing the “ecotourism as a western construct,” it is noted that “the social appropriation of nature must be viewed in, and from, particular social, economic and political contexts. Failure to do so will only result in continued disappointment, frustration and resentment over the manifest shortfall between what ecotourism promises and what it delivers” (Cater 2006).

As indicated by Cater (1995), tourism is an industry which has many connections with many sectors and interests on varied levels while executing the operations, and it is suggested to increase the positive links of tourism with environment and to break the negative links by the accountancy procedures such as environmental auditing. In a study realized in Couran Cove Island Resort and Boondall Wetlands Reserve, Queensland, Australia, five types of environmental indicators proposed for the detailed and exhaustive checklist of tourism projects: “Fragility of ecosystems and biodiversity, waste disposal, water consumption, intensity of land use and physical impact, protection of the atmosphere, noise level and visual impact” (Lim and McAleen 2005). In another study, the extent to which certain criteria about the destination environmental competitiveness can be useful is discussed, and measures are suggested such as environmental impact and environmental quality management. In this same study, environmental quality management is divided into subcategories: “management by codes of conduct, by self-developed environmental practice, by certified or awarded best practice and by accreditation schemes” (Mihalic 2000).

Any destination should adopt sustainable practices in today’s fragile environmental state of the world. However, specifically for the natural reserves within a much more vulnerable ecological system which are opened to tourism, it is a must to create “balance between climate change, tourism growth and environmental protection” (Sun et al. 2019). Similarly, to create this balance and to reach correctly practiced ecotourism

activities, another study made in Indonesia signals that “social entrepreneurship” plays a key role (Situmorang and Mirzanti 2012). Unfortunately, it is found out that a major part of the carbon emissions were produced as a result of the commercial activities of tourism operations in the case of Jiuzhai Valley in China (Sun et al. 2019).

Another important aspect that needs to be studied and researched more to combine the environmental protection aspect with the ecotourism is “ecological restoration” (ER). Blangy and Mehta (2006) showing the example cases from Belize and Central Africa attract the attention to the importance of the ecological restoration, ecodolges, and the creation of linkage between ecotourism. This connection together not only creates livelihoods in the little localities that otherwise would be deserted for the city center but also contributes to the revival of the biodiversity. Additionally, the voluntary participation of the tourists supports this fruitful win-win scene (Blangy and Mehta 2006).

Tourism activities influence climate change at the global scale (Wang et al. 2019). The contribution of CO₂ produced by energy consumption associated with tourism activities to climate warming is between 4.6% and 7.8% (UNEP and UNWTO 2008). Tourism also causes water shortages on the regional (Gössling et al. 2012) and local scales (Cole 2014) and ecological deficits at some tourism destinations (Castellani and Sala 2012).

The impacts of tourism activities on the environment have begun to be measured more concretely in the more recent studies such as Wang et al. (2019). It is promising as well as difficult to conduct this type of a multidisciplinary study and is very well needed by the sector as well as by the world, to pay the costs incurred to environment and to take precautions for the future of tourism and the survival of the world. In this study, “tourism heat footprint” (THF) method is applied in order to find out the heating effect of “accommodation, catering, transportation, human body, sight-seeing, entertainment, shopping, and waste disposal” on glacial changes. The results

of the study show that “In the context of global climate change, the THFs generated by large-scale tourism activities within the Yulong and Hailuoguo tourism zones have significant local temperature increasing effect. And these temperature increases have had a cumulative effect on glacial changes. This effect is contrary to the sustainability of glacial tourism and destinations” (Wang et al. 2019).

Environmental Accounting

Maria-Gabriella Baldarelli

Department of Management, University of Bologna, Rimini, Italy

Synonyms

Accounting for the environment; Ecological accounting; Environmental cost accounting; Waste management accounting

Definition

Environmental accounting is the process that determines and accounts for the impact that

organizations and companies have on the, mainly ecological, environment. Once having activated the process of determining and accounting for the environmental variable, the organization and company need to translate this initial choice into a trend to consider in all long- or short-term decisions made by them. Rather, it is a matter of accounting for the consumption and depletion of natural or environmental resources (Baldarelli et al. 2017). In order to activate this process, which is also termed eco-efficiency (Burrit and Shaltegger 2001), there may be various methods foreseen, among which are the need for the organization to hold an environmental certification, the will of the property and/or managers, as well as other causes.

Once having activated the process of determining and accounting for the environmental variable, it is necessary that the organization and company translate this initial choice into a trend to consider in all long- or short-term decisions made by them.

This process allows us to consider the organization and company approach directed toward the reduction and/or recovery of environmental harm caused by their activity. Such an approach may be defined as “weak” in relation to depletion of environmental resources.

As an alternative to the previous one, we may consider a certain company behavior directed toward preventing and improving environmental resources adopting this logic in the long-term strategic trend. The organization must involve the environmental variable in decision-making process. The environmental variable must become the essential element of company mission and governance along with financial and economic ones. This second approach can be defined as “strong.”

Measurement of Environmental Variable: Conceptual Network

The environmental variable can be measured and disclosed following these different dimensions where progressively we can have financial

measures, intermediate measures, and integrated measures (Baldarelli et al. 2017).

Financial measures are inside of the financial statement, so they don't appear and remain as a sort of shadow accounting. Intermediate measures consider both those that are inside of the financial statement and those that are elaborated using other information (Baldarelli et al. 2017).

Integrated measures consider some indicators that are relative to involve statistics elaboration using physical and economic indicators (Baldarelli et al. 2017).

Environmental accounting, from the standpoint of accounting measurement and financial reporting, considers environmental costs, environmental revenues, and environmental budget (Burrit and Shaltegger 2001).

Environmental costs measure: “Resources expended to evaluate, prevent and correct ‘shortcomings’ deriving from actions which, potentially, generate a negative effect on human, animal and vegetable life” (Miolo Vitali 2009:230). They are based on the natural resource to which they are addressed – water, air, soil, waste, and noise – and can be internal and/or external environmental costs.

Some examples of environmental costs are management of waste and external emissions, training on environmental topics, research and development linked to the environment, and workers' safety as well as their satisfaction (Mio 2002).

Environmental revenue derives from the “sale” of goods that were previously regarded as disposal costs, such as ecological bales of recycled material, such as plastic, paper, and glass.

The environmental contribution margin is very important to compare the traditional calculation of the contribution margin, that is the result of the unitary price of sale less variable cost per unit, with the environmental emission for each product or service. So the evaluation of the best product/service not only is based on economic calculations but is considering the environmental variable too, such as pollution and waste.

The environmental budget is the account that contains quantitative results concerning the environmental impact of the enterprise, such as

environmental revenues, environmental costs, costs of environmental management, and environmental investments (Mio 2002; Shrivastava 1995; Porter and Van der Linde 1995).

Costs of environmental management are relative to the development of internal responsibilities concerning environmental damage that the organization or company has caused.

Environmental investment is an implementation process by which the company expects to produce a more positive impact on the environment.

From Environmental Accounting to Weak and Strong Approach

At the current state of the art, different company behaviors may be listed between the “weak” and “strong” approaches.

Only by having eco-efficiency permeate throughout company culture, it is possible to affirm that the company will adopt the environmental variable in all decision-making aspects as well as in all management control activities with its relative tools.

This process may be developed by following various stages, though it is, nevertheless, necessary that the organization or the company gradually separates environmental accounting from the financial one. This is because, in financial accounting, information regarding the environmental variable only emerges indirectly. In environmental accounting, on the other hand, information concerning the environmental variable is stated by following methods and criteria that are both accounting and extra-accounting ones, amongst which are statistical indicators. This allows environmental accounting to acquire the inter-disciplinary nature to contribute to complete environmental information.

Summary

In this entry the meaning of environmental accounting is explained involving some tools to

measure and disclose environmental variables and information by organizations and companies. That information is not immediately available in financial statements, but it is required to record them in a separate environmental accounting. Among them, the definition of environmental costs and revenues, environmental contribution margin, and the environmental budget are included.

Definitions

Environmental assessment is a concept that is often confused with Environmental Impact Assessment (EIA) and Strategic Environmental Assessment (SEA) (Arts and Morrison-Saunders 2012). Environmental Assessment is a term broadly used to describe the various systemic

assessments conducted by experts to identify, estimate, and evaluate the environmental impacts associated with the disparate human activities to mitigate likely negative effect and support decision making (Andersson et al. 2016; Jain et al. 2012). It is a tool for integrated environmental planning where the sociocultural, economic, and ecological systems of the world are brought to perspective (Gnansounou and Raman 2019). EIA and SEA are examples of the many approaches used in environmental assessment. While EIA is an anticipatory and participatory method for identifying, predicting, and analyzing the possible impacts of a proposed project on the physical environment, as well as the associated social, economic, and health impacts, SEA is a set of analytical and participatory processes for incorporating environmental considerations into policies, plans, and programs that might have impact on the environment. Other common tools include Life Cycle Assessment (LCA) and Material Flow Analysis (MFA) (Andersson et al. 2016; Gnansounou and Raman 2019).

Introduction

The era of industrial revolution was largely characterized by a high-income economy, improved standards of living, and technological breakthroughs such as steam power, textile, communication, and transport technologies, among others. However, these gains came with a number of environmental concerns: air pollution, water pollution, climate change, hazardous waste, and land degradation (Todua et al. 2006; Salami 2019). It was only in the last third of the twentieth century that the negative consequences of human development and industrialization on the overall earth's ecological balance were duly recognized (Ambala et al. 2006; Essays, UK 2018). To therefore maintain the long-term viability of the environment to sustain life, conscious efforts were made to increase environmental awareness and environmental factors began to play a significant role in development planning while stringent environmental regulations were enacted. In 1962, environmental awareness began to receive a stronger

public and global impetus following the publishing of Rachel Carson's book titled "The silent spring." This publication, in simple terms, beamed light on the harmful implications of growing use of pesticide on the global environment and its sustainability. The "Silent spring" is believed to have motivated the launching of a massive movement that consistently put pressure on governments and led to the evolution of the practice of environmental assessment (EA) (Modak and Biswas 1999; Matemilola et al. 2019).

EA affords the opportunity to provide evidence-based approaches to support decision-making as it relates to the protection of the environment and public health (Jain et al. 2012). Also, it encompasses several processes such as negotiation, participation, and monitoring that are essential in the identification of the likely environmental impacts of a proposed human activity and how they can be mitigated. These impacts can either be direct, indirect, or cumulative (Modak and Biswas 1999). A direct impact is as a result of the direct interaction between an activity with an environmental, social, or economic component. While an indirect impact is a secondary impact that arises as a result of changes to a direct impact through complex pathway. A cumulative impact is defined as the result of additive and aggregative actions producing impacts that accumulate incrementally or synergistically over time and space. It is pertinent to note that besides impacts identification and prediction, EA enhances and strengthens the relationship between government, industry, environmentalist, and the public through the exchange of information, public participation, and the recognition of susceptible environmental factors (Ambala et al. 2006; Modak and Biswas 1999).

Environmental Factors

Prior to the assessment of the impacts of a proposed activity on the environment, the prerequisite requirement is to identify and describe the environmental characteristics that might be affected by such activity. Notable environmental factors include surface and sun-surface water,

land, air, plant, animal life, etc. Consideration is also given to socioeconomic factors such as income, number of jobs, and future land use (Modak and Biswas 1999).

Environmental Assessment Tools and Methodologies

The complexities and dynamics involved in the technical systems process of decision-making to engender sustainability have brought about the evolution of various environmental assessment tools over the last three decades. These tools are built on a system perspective to create a decision support system for policy formulation in the public sector and for investment and strategy decisions in the private sector (Weiner and Matthews 2003; Andersson et al. 2016). Depending on the context, scope, and scale application, and the targeted environmental system, environmental assessment can be achieved with various tools/methodologies including: life cycle assessment (LCA) for assessment of products and services, material flow analysis (MFA) for evaluation of flow of resources in a specified region, cumulative impact assessment (CIA) for identifying additive and interactive effect (Andersson et al. 2016), strategic environmental assessment (SEA) for examining the potential implications of proposed policies, plans and program on environmental components (Loayza 2012), and environmental impact assessment (EIA) for evaluating environmental and socioeconomic impacts of proposed development (Morgan 2012).

An LCA involves the quantification of the impacts of products and services on the environment. It entails the evaluation of the resources consumed as well as the associated emission throughout the life cycle of such a product or service. LCA was defined and standardized by the International Standards Organization (ISO) within the procedural framework of ISO 14040–14043, and it has four major stages, namely goal and scope definition, life cycle inventory, life cycle impact assessment, and interpretation.

MFA, also known as material and energy flow analysis (MEFA), allows for the comparison of

processes or products by determining the energy and mass balance. This method establishes the input-output relationship and assumes that the higher the quantity of resources used, the higher the impact (Andersson et al. 2016).

EIA is a tool for identifying the environmental and social impacts at different phases (construction, operation, and decommissioning) of a proposed development in order to evaluate alternative approaches, and to design mitigative, management, and monitoring measures. EIA is carried out to ensure that avoidable environmental damages are not caused by a proposed development (Essays, UK 2018).

CIA is concerned with the assessment of the potential environmental and social impacts that may result from the combined influence of more than one human activity (Weiner and Matthews 2003). Here, impacts are viewed from a broad system-wide perspective. CIA is usually carried out as part of an EIA, and this is necessary to determine potentially significant consequences of a proposed development in combination with other activities or projects (Andersson et al. 2016).

SEA, unlike other tools, is concerned with the systemic evaluation of environmental implications of proposed policies, plans, or programs. It provides the opportunity of identifying avoidable effects at the earliest stage of decision-making (Loayza 2012).

However, because these tools have different applications and targeted systems, their structure, procedures, and method of presentation of results also differ. Thus, environmental assessment tools are classified into procedural, analytic, and aggregated tools (Fig. 1).

- I. Procedural tools: These tools are usually used for integrating environmental, economic, and social factors in decision-making and ensuring stakeholders' engagement in reaching a consensus solution. Examples are Environmental Impact Assessment (EIA) and Strategic Environmental Assessment (SEA).
- II. Analytical tools: These are often standardized tools for calculating and quantifying material, energy, and economic flows. A good example is Life Cycle Assessment (LCA) which is standardized in ISO 14040 and 14044.

Adapted from: Andersson, et al. (2016)

Environmental Assessment, Fig. 1 Classification of environmental assessment tools (Adapted from: Andersson, et al. (2016))

III. Aggregated tools: These types of tools are designed for easy monitoring and communication of complex systems. Such tools aggregate technical information into a format that can be clearly and easily communicated and interpreted. Examples are indicators and indices.

Summary

Environmental assessment or environmental systems analysis fast became a veritable decision-making tool with the growing need for structured handling of complex systems relating to global environmental concerns. The system perspective of EA has led to the evolvement of several assessment tools that were standardized. Commonly used EA tools are life cycle assessment (LCA), material flow analysis (MFA), environmental impact assessment (EIA), Strategic Environmental Assessment (SEA), cost benefit analysis (CBA), and carbon footprint.

Definition

Rapidly increasing pollution levels, over exploitation of natural resources, accumulation of toxic waste, soil erosion, and continuous environmental degradation have become some of the major environmental concerns these days impacting biodiversity, ecology, and quality of life on the Earth. It has been realized that industry and business are the key contributors to this grave situation and must now take responsibility for their actions and practices harming environment. Public concerns on these issues have led to enactment of

various laws and regulations at national and international levels requiring business to reduce their adverse environmental impacts. Violation of these statutes can result in hefty penalties, stringent legal action, and even closure of business. Large number of companies across the world have started designing their environment policies, programs, and management systems to prevent and control emissions, preserve natural resources, and reduce environmental impacts. With these legislative and social trends, assessment of environmental performance for ensuring compliances has become an important part of an organization's environmental management system (EMS) so as to mitigate environmental risks and related environmental liabilities. Environmental compliance audits are conducted to verify that a company's operations and practices are in compliance with applicable environmental laws, regulations, standards, and company's own environmental policies. Such audits not only help organizations to assess their current compliance status, but also lead to timely detection of noncompliances so that corrective actions can be taken to improve compliance position.

Introduction

The term environmental auditing has its origin in the 1970s, when companies in the USA started undertaking voluntary environmental audits to evaluate their environmental performance and to avoid remediation costs and fines (EPA 1997). Cahill and Kane traced the beginning of the use of environmental auditing as a management tool in the 1970s for actions taken by the Securities and Exchange Commission (SEC) which led public companies in the USA to perform internal environmental audits to find the extent of their environmental liabilities (Cahill and Kane 1989). This played a significant role in establishing environmental auditing as a key compliance verification practice in the USA. During the late 1980s, when environmental issues started getting attention at international levels, these audits became popular in other countries also. Since, 1996,

International Standard Organization (ISO) has issued number of standards on environmental management and audit systems. ISO 14000 family of standards on environmental management provide guidance to entities on general principals to be followed in managing their environmental responsibilities and in execution of environmental audits (ISO n.d.). Adoption of these standards by companies has provided an impetus to the use of environmental audits. In the twenty-first century, companies across the world have started going for voluntary environmental audits to deal proactively with environment-related issues.

Different authors have defined the term environmental audit differently. One of the commonly accepted definitions of environmental audit was given by the International Chambers of Commerce (ICC) in 1989. According to (ICC 1989), “Environmental audit can be defined as a management tool comprising a systematic, documented, periodic and objective evaluation of how well environmental organization, management and equipment are performing with the aim of helping safeguard the environment by a) facilitating management control of environmental practices; and b) assessing compliance with company policies which would include meeting regulatory requirements.” These audits are used by the management to check efficiency and effectiveness of a concern’s environmental management system in meeting its environmental targets. Environmental audits also help in evaluating concern’s compliance with the applicable environmental laws.

There are broadly three types of environmental audits, namely, environmental compliance audits, environmental performance audits, and environmental financial audits (INTOSAI, WGEA 2007). Environmental compliance audits are conducted to ensure compliance with pertinent environmental laws and regulations to which an organization is subject in order to reduce/eliminate environmental risks and potential environmental liabilities. Environmental performance audits aim to assess whether an organization is effective in producing desired environmental results in a cost-efficient manner. The purpose is to ensure application of environmental policies, practices, and

management systems in such a way so as to improve overall environmental performance of the organization. Environmental financial audits are conducted to verify accuracy and authenticity of environmental financial information given in different documents, statements, and reports prepared by a concern. These audits aim at ensuring that all material environmental costs, benefits, assets, liabilities, and contingencies are duly recognized, properly valued, and adequately reported to the concerned stakeholders.

Environmental Compliance Audit

The most common type of environmental audit is environmental compliance audit. The definitions of environmental audit given by many agencies have emphasized the compliance aspect of environmental audits.

According to US Environment Protection Agency (EPA), “Environmental auditing is a systematic, documented, periodic and objective review by regulated entities of facility operations and practices related to meeting environmental requirements” (EPA 1986).

According to the World Bank, “Environmental audit is a methodical examination of environmental information about an organization, a facility or a site to verify whether or to what extent, they confirm to specified audit criteria. The criteria may be based on local, national or global environmental standards” (ASOSAI 2006).

Thus, environmental audits are usually conducted to verify compliance status of an entity as required by legislation, standard, agreement, or as defined under company’s environmental policy. Environmental compliance audits are different from routine audit of a concern’s EMS or environmental impact assessment (EIA). EIAs are mostly conducted before commencement of a project to predict its potential environmental effects, whereas a routine periodic examination of EMS aims to prevent and control adverse environmental impacts and, thereby, improve environmental performance of the organization. These are usually internal audits. The focus of environmental

compliance audit is on compliance aspect of company's operations. However, the results of EIA can be used by compliance auditors.

Objectives of Environmental Compliance Audits

Businesses these days are subject to number of legal requirements relating to environment. These requirements may range from obtaining emission permits, submitting environmental due diligence certificates, disclosing information on chemical leaks, handling of hazardous material or disposal of toxic waste, and filing various documents with regulatory authorities. Many businesses especially small and medium enterprises (SMEs) find it difficult to comply with these requirements as these are mostly technical and complex. Keeping track of frequent changes in existing legal requirements as well as new environmental regulations is another challenging task. In the recent years, regulations have become more stringent, authorities are putting lot of efforts to ensure strict enforcements, and chances of detection of non-compliances have increased significantly. Non-compliances may lead to huge financial, legal, and reputational loss for business as well as management. To avoid legal actions and penalties arising from failure to comply with environmental regulations, companies across the world have started using compliance audits as a preventive tool. The basic purpose of an Environmental compliance audit is to reveal any actual or potential environmental violations and to alert the corporate management so that necessary remedial actions can be undertaken on time (Majumdar 2011). The compliance auditor aims "to develop and implement an environmental compliance audit program in such a way so as to avoid administrative, civil, or criminal fines, penalties, or injunctions" (Lucks 2017). Thus, an environmental compliance auditor checks compliance status of existing operations, detects current and potential compliance gaps, and suggests remedial measures so that these gaps can be corrected on time before any action is taken by regulatory authorities leading to real environmental liabilities.

Types of Environmental Compliance Audit

An environmental compliance audit can be voluntary or mandatory. Voluntary environmental compliance audits are preventive in nature. These are conducted by organizations proactively to detect variations from legal requirements and to design remedies before these deviations convert into liabilities. Mandatory compliance audits are compulsory under some statute. Environmental audits are voluntary in most of the countries (Majumdar 2011). Unlike statutory financial audits which are mandatory in many countries, usually there are no regulatory requirements for companies to go for environmental compliance audits. These audits can be conducted by a team of internal auditors who are specially appointed for this purpose. But management in big companies often prefer that environmental compliance audits are conducted by external independent auditors as noncompliances to environmental laws may mean huge risk for top management who are mainly responsible for legal compliances.

Further, an environmental compliance audit can be multimedia or specific audit. While a multimedia compliance audit deals with all environmental regulations applicable on a business (e.g., laws relating to air, water or noise pollutions, energy conservations, management of hazardous waste, emissions, etc.), a specific compliance audit is concerned only with one specific law or regulation. Carbon audit, permit audits, specific requirement audits, certification audits, surveillance audits, audits for eco-labeling, audits under ISO, safety and health audits, and GHG audits are examples of specific compliance audit.

Benefits of Environmental Compliance Audits

Environmental compliance audits result in number of benefits for the organization. These audits are conducted with the objective of helping management in ensuring compliance with applicable environmental statutes, environmental standards, and companies' policies and, thereby,

facilitate controlling of environmental risks, costs, and liabilities. Some other benefits of environmental compliance audit include the following:

- Helps management in understanding complex legal requirements and designing environmental policies and EMS accordingly
- Helps in timely submission of environmental compliance data to regulatory authorities
- Increases awareness of employees and management about number of pertinent environmental issues
- Leads to conservation of scarce resources and reduction in related costs
- Helps in improving environmental performance of the company
- Gives competitive advantage to the company through green production and marketing
- Helps in meeting stakeholders' expectations and enhancing their confidence in the company
- Improves public image of the concern
- Helps in getting due diligence certificates which may be required at the time of getting loans, permits, and grants
- Helps to minimize health and safety hazards in factories and retaining workforce
- Helps in improving emergency response system and disaster management

Compliance audit reports can be used to fight cases of damages and injuries filed against companies by third parties for violation of environmental laws. If on the basis of environmental compliance audit report, a concern decides to report past noncompliances to authorities voluntarily, it may request for lenient settlements from authorities (Majumdar 2011). Regulatory authorities also encourage such voluntary reporting as without going for detailed checks and tedious site inspections, they can get to know about compliance status of the organization. These audit reports can also be used by financiers, property buyers, investors, and other stakeholders who might be interested in knowing about environmental compliance status of the organization before dealing with it.

Compliance Audit Process

Like any other audit, environmental compliance auditor also follows a standard procedure for auditing which starts with preaudit steps and goes till submission of audit report. Important aspects of this process include determination of:

Audit objective: The objective of compliance audit is to verify whether activities of the organization are in compliance with environmental laws, standards, and company's proposed plans and strategies. The focus area may be all environmental laws or a specific environmental law or regulation.

Audit criteria: National and international environmental laws, regulations, rules, agreements, applicable standards, ordinances, codes, disclosure requirements, and corporate policies.

Scope of audit: Scope and frequency of an environmental compliance audit depend upon nature, size, and complexity of business and prudence of the auditor.

Audit team: It should consist of members having technical knowledge about environmental issues, legal expertise, and knowledge of audit procedures.

Preparation of audit plan and protocol: An auditor can make his own checklist or use standard protocols.

Obtaining knowledge about business activities, relevant environmental laws, compliance history, company's environmental policy, goals, environmental management and audit system, internal controls, etc.

After going through these steps, an auditor performs onsite audit. Information is collected through documents, files, records, questionnaires, forms, interviews, etc. Both analytical and substantive procedures are used to collect and analyze data against set audit criteria. After thorough analysis of collected data, the auditor drafts his report which is placed before management for discussion. Once management gives it approval, a final report is prepared and submitted. It is expected that a high quality compliance report should not only highlight noncompliances but also contain recommendations for improvement in current and potential compliance status. This report provides

Process of Environmental Audit

Environmental Compliance Audit, Exhibit 1 Process of environmental audit. (Source: Pahuja (2013))

the basis for improvement and benchmarking. Periodical review and follow-ups are done to see if recommendations are implemented. Exhibit 1 outlines steps involved in environmental compliance audits:

Summary

Due to ever increasing environmental laws and regulations, compliance and compliance audits have become the latest buzzword in the environmental community (Majumdar 2011). In today’s regulated environment, ignorance of law cannot be taken as an excuse for noncompliance. Violations and noncompliances may bring huge legal, financial, and reputational repercussions for a company and its management. There are growing social and legal pressures on the business to take steps to prevent and reduce harmful impacts of its operations on the environment. In this scenario,

conducting an environmental compliance audit is no longer optional for an organization. Environmental compliance audits are increasingly being used by corporations across the world as a sound precautionary and preventive measure to ensure the effectiveness of EMS in dealing with compliance issues. Now these audits are being designed in such a way so as to go beyond detecting noncompliances in existing operations. Focus these days is on proactive management of EMS for regular, periodic assessment of company’s operations in order to reduce compliance gaps, control environmental risks, reduce environmental costs, and improve environmental performance of the entity.

Definition/Description

Disasters are defined as events that can originate from both nature and humans although the line between the two can blur, producing “unnatural” disasters (Bates 2002). Geological, hydrological, and atmospheric disasters such as earthquakes, volcanic eruptions, landslides, rocks falling, avalanches, drought, flooding, storms, lightning strikes, and hurricanes are considered to be natural disasters (Adeniran 2013). Environmental disasters are man-made, anthropogenic ones; it means that they are caused by human activity. Human activity can change the environment abruptly or gradually (Bates 2002). Environmental disasters affect agriculture, biodiversity, the economy, and human health. Unnatural disasters are result from an interaction of natural and anthropogenic disruptions in the environment. According to Jacobson (1988, p. 16), they are “normal events whose effects are exacerbated by human activities.” Technological disasters are entirely anthropogenic, but like natural disasters, they are temporally acute (Bates 2002). Environmental pollution or depletion can produce also the anthropogenic deterioration of an ecosystem (Schnaiberg and Gould 1994).

Introduction

The quality of the built environment, both natural and man-made, depends on its management, that is, its process of control, and organization. According to Adeniran (2013), there can be forces that cause events that lead to unsafe built environment for water, land, and air inhabitants. While these forces are generally categorized into natural and man-made, their resultant effects are multifarious, calamitous, and disastrous. These resultant effects are generally called disasters (Adeniran 2013). Disaster occurs in different parts of the world at different times and in various scales leaving behind various magnitude of loss to lives and properties. A natural disaster is the consequence of a natural hazard (Bhargava 2011) which affects human activities. An anthropogenic or man-made disaster is a result from technological inventions or from civil conflicts. Disasters may also occur from natural forces like earthquake or volcanic eruption acting negatively on man-made inventions like buildings, boats, ships, cities, and artificial islands. Such disasters are called unnatural disasters (Adeniran 2013).

The aim of environmental management is to reduce or completely eliminate the vulnerability of the environment to disaster through prevention, mitigation, preparedness, or capacity building. In the European Union (EU), it has been emphasized the idea about to make individuals and local communities more reactive and better equipped to cope with catastrophes (Amaratunga et al. 2015). The European Commission (EC) (2013) in its part has identified awareness-raising of the general public to be important concerning disaster prevention. Disaster education is a critical basis for resistance and recovery in many disasters because emergency agencies may not be able to help all people.

Key Issues

Disasters are defined as events that can originate from both nature and human beings and cause

Environmental Disaster, Fig. 1 Disaster types (Adeniran 2013; Bhargava 2011; Gunn 2004)

losses of life, property, and social value, as well as stopping or interrupting human activities (Bates 2002) (Fig. 1).

Natural environmental disasters are any natural occurrences that cause widespread distress, usually including loss of human life and notable damage to socio-ecological systems and property (Bhargava 2011). They may cause large-scale damage from which recovery is either impossible or long term. They have the power to shake the universe. Natural environmental disasters can happen at any time or place. They are the consequence of natural hazards. A hazard is a situation which poses a level of threat to life, health, property, or environment (Bhargava 2011). Examples of hazards are volcanic eruption, earthquake, landslide, flood, cyclones, cold waves, drought, thunderstorm, heat waves, mudslides, and storms which affect human activities. Gunn (2004) shows that although technology has given humankind enormous control over the environment, it has also proven to be a threat to our survival.

Environmental Disaster, Fig. 2 (a, b) Deterioration of environment. (Photos: E. Jeronen)

Environmental disasters (man-made or anthropogenic disaster) are results from technological inventions and civil conflicts (Adeniran 2013). According to Adeniran (2013), examples of the previous ones are aircraft, automobiles, and industrial developments and the latter ones riot, unethical, non-professional, and careless endeavors like fire outbreak, damaged pipelines, building collapse, chemical spill, road accident, food poisoning, epidemic industrial disaster, crisis, deforestation, war, environmental pollution, and plane crash, among others. Gunn (2004) categorizes the environmental disasters into a number of subtypes – for example, industrial explosions, mining disasters, dam failures, oil spills, nuclear energy catastrophes, and terrorism. Still yet, disasters may occur as a result from an interaction of natural and anthropogenic disruptions in the environment. Unnatural disasters are again deaths and damages that result from human acts of omission and commission (Adeniran 2013).

Natural, environmental, and unnatural disasters may affect catastrophic event that causes a lot of casualties, injuries and deaths, and destruction of human property and disturbs ecosystems stability (Bhargava 2011). The anthropogenic deterioration of an ecosystem may be caused by either pollution or depletion (Schnaiberg and Gould 1994). Pollution means the presence of pollutants (e.g., substances, noise, radiation,

contaminating pathogens) in the environment in such a quantity, concentration, or duration, that may cause harm on human health, on the proliferation of living organisms and on the equilibrium of ecosystems, making the environment unfit for human use. Pollution threatens the quality of life, the preservation of cultural heritage, and the aesthetic values of communities (Bhargava 2011). Depletions may concern only a single species in a given environment (Schnaiberg and Gould 1994). Direct additions stem from the release of toxic substances into the environment that gradually affect ecosystems and human life (Bates 2002). According to Bates (2002), deterioration of environment may also be a result from the gradual removal of some part of the ecosystem (Fig. 2a and b). As depletion worsens, the people who depend on this resource have to search for some way to compensate. For example, farmers may practice agriculture that depletes soil fertility at a rate that exceeds the ability of the soil to replenish itself. As harvests decline, these farmers must find other ways to produce food or income. This process is demonstrated well in places where intensive agriculture has expanded into inappropriate environments, such as deserts and tropical rainforests.

Negative impact of pollution on the equilibrium, the quality of life, the salvage of cultural heritage, and the aesthetic values of human communities is called degradation (Bhargava 2011). Gradual degradation of the atmosphere by

additional carbon dioxide and other greenhouse gasses again may cause sea levels to rise as much as 1 m by the middle of the next century (Myers 1993, 1997). This process is due with the current global warming trend that is human expansion of the “greenhouse effect” – warming that results when the atmosphere traps heat radiating from Earth toward space (NASA 2018; Oreskes 2004).

Disasters occur in different parts of the world at different times and in various scales leaving behind various magnitude of loss to lives and properties. Damage and death tolls can be assessed, but it is impossible to place a price on the socioeconomic effects on the world as a whole. Psychological impact, cultural treasures, and human potential are things that can never be recovered. Disasters’ potential hazards are not preventable, but their damage can be reduced, and humans’ abilities to cope with disasters can be increased. Because human behaviors surrounding the issue of coping with unforeseen events are related to each individuals’ levels of preparedness, knowledge, and consciousness, identifying levels of knowledge and awareness about disasters, and working to increase their knowledge and awareness, will provide preventive and protective support for societies (Dikmenli et al. 2018). Disaster awareness is not limited to taking action during or after a disaster but also includes taking necessary precautions and making preparations before disasters begin.

Concepts such as security culture, risk culture, and preparation culture are disaster awareness-related concepts. With this in mind, education is used intensively to spread disaster culture in society (Benadusi 2014). Disaster awareness can be taught both to children (Johnson et al. 2014) and adults (Preston 2012). Besides the development of a greater awareness of the risks and more detailed technical knowledge about disaster, it is important to involve the population in identifying the specific threats inherent in their local context and the most appropriate solutions for mitigating them (Benadusi 2014). According Preston (2012, p. 1), disaster education “includes not only school-based initiatives and public information campaigns but also family and community learning, adult education and popular culture.” This

can be best achieved through the dynamic and sustained involvement of all concerned parties (Djalali et al. 2014; Wang 2016). New disaster education strategies are designed to stimulate the ability of individuals and social groups to protect themselves in cases of catastrophe (Benadusi 2014). If disaster awareness can be raised in all people, protective and preventative behaviors against disasters will be developed, which will minimize the damage and loss of life and property from threats that may arise from disasters. People with disaster consciousness have enough information about disasters and may be aware of potential threats and risks and consequently can make an action plan for disasters and act correctly during a disaster. Empowerment of citizens can be developed with continued education, efforts, and campaigns concerning environmental awareness.

Community disaster education is an integral component of disaster management around the world. Its main goal is to promote public safety. It also seeks to reduce damages caused by disaster and to build community disaster resilience (Dufty 2012). Disaster resilience means the ability of a community not only to resist and recover from a disaster but also to adapt to the changes that the event may cause. It includes the ability of a community to learn from the disaster and to improve its networks, systems, and capabilities for the next event. So, the term “disaster education” can be used for all education, communications, and engagement activities that lead to learning before, during, and after an emergency or disaster (Dufty 2018). Disaster education should be tailored to the individual’s and local community’s learning needs. Individually, it may begin developing understanding of individual ecological footprints. The ecological footprint accounts document how much of the annual regenerative capacity of the biosphere, expressed in mutually exclusive hectares of biologically productive land or sea area, is required to renew the resource throughput of a defined population in a given year – with the prevailing technology and resource management of that year (Monfreda et al. 2004). In local community education, Webber et al. (2017) emphasize participative engagement and learning related to all aspects of local emergency management

planning. Subsequently, good environmental practices should be included to people's lifestyle.

Summary

Disasters are defined as events that can originate from both nature and human beings and cause losses of life, property, and social value, as well as stopping or interrupting human activities. Natural disasters are the consequence of natural hazards, and they can happen at any time or place. Environmental disasters (man-made or anthropogenic disaster) are results from technological inventions and civil conflicts. The release of toxic substances into the environment can have acute or gradual effects on ecosystems and human life. Technological disasters are entirely anthropogenic, but like natural disasters, they are temporally acute. Gradual degradation of the atmosphere by additional carbon dioxide and other greenhouse gasses again is due with the current global warming trend that is human expansion of the greenhouse effect. Depletions may concern only a single species in a given environment or degradation of the ecosystem as a whole.

Disasters' potential hazards are not preventable, but their damage can be reduced, and humans' abilities to cope with disasters can be increased. Disaster awareness can be taught to all members of a society. Disaster education includes both school-based initiatives, public information campaigns and also family and community learning, adult education, and popular culture. People, who are aware of disaster threats and risks and have knowledge about disasters, may have protective and preventative behaviors against disasters. Consequently, they can make an action plan for disasters and act correctly during a disaster which will minimize the damage and loss of life and property caused by disasters.

Environmental Disclosure

Selena Aureli
Department of Management, Bologna University,
Bologna, Italy

Synonyms

Carbon accounting reporting; Environmental reporting; Green accounting and reporting

Description

Environmental disclosure refers to the voluntary or mandatory communication of information that shall help company's stakeholders to recognize the impact of business decisions on the environment. Disclosed information usually includes narratives about company's environmental programs and policies, compliance with local environmental legislation, achievement of environmental certifications or awards, adoption of environmental management systems, description of environmental risks, as well as quantitative information like environmental indicators or measures related to the amount of waste produced, the usage of natural resources, emissions, company expenses, and investments made to reduce possible negative impacts on the environment. This information can be found in annual reports, stand-alone environmental reports, or sustainability reports. In addition, companies may be obliged to disclose specific environmental information to the public, government authorities, or agencies to account for their ecological footprint. For example, in the United States, most manufacturing firms and utilities are required to provide to the Environmental Protection Agency (EPA) annual estimates of toxics released into the environment and the EPA makes this information publicly available.

Corporate Environmental Reporting: From Voluntary to Mandatory Obligations

Company' disclosure on environmental aspects has moved through years from simply demonstrating a company's commitment to the environment to communicating rich environmental performance data.

According to Fifka (2012), corporate practice of disclosing environmental information dates back to the 1980s when Western companies began to focus on emissions and waste generation caused by manufacturing activities. The first companies to release stand-alone environmental

reports were those in the petrochemical sector, while the mining sector started producing dedicated reports more slowly in the 1990s. In that period, companies had to respond to stakeholders that began scrutinize companies operating in environmentally sensitive industries such as energy and mining, which were responsible for oil spills, blowout, and other disaster causing severe consequences for people and wildlife (Patten 1992; Darrell and Schwartz 1997).

Then, by the end of 1990s, corporate reporting started considering the social and the environmental dimension simultaneously in a joint report attached or published alongside traditional financial reports. After Elkington's (1998) triple-bottom-line concept of people, planet, and profit, companies have actually began to adopt reporting standards and frameworks, like the GRI's sustainability reporting framework first launched in 2000, that suggest to jointly disclose social, environmental, and economic aspects.

Environmental disclosure has been a voluntary practice for many decades. The reason for such practice was attributed to the fact that the publicly available information was incomplete, too much focused on financial aspects, and did not allow investors to adequately assess who are the best companies; therefore, better performers are willing to disclose environmental information to signal their superior position. A competing explanation indicates that companies use voluntary environmental disclosure to reduce their exposure to social and political pressures by projecting an image of environmental awareness.

According to the latest explanation (base on legitimacy theory), companies operating in environmentally sensitive industries such as oil and gas, chemical, and forestry are considered to be more active in providing environmental information because they need to legitimize their actions in the eyes of society (Niskanen and Nieminen 2001; Patten 1991; Neu et al. 1998). In other terms, environmental disclosure is a mean of addressing the exposure firms face with regard to the social environment. Consequently, the worse the environmental performance is, the greater

company disclosure will be (Aerts and Cormier 2009).

Environmental disclosure has been mainly a voluntary practice but several national governments already introduced requirements related to specific aspects, sometimes limited to selected industries or types of companies. Norway is a pioneer in this field as it introduced environmental reporting regulations in 1989. However, the Norwegian Accounting Act that specifies which enterprises are subject to environmental regulation imposed only a general obligation (i.e., to provide information pertaining to the environmental impact of running the business, including inputs and products) and delegated to the national accounting standard body the description of requirements. Denmark issued its Green Accounts Act in 1995 that required about 1200 high-pollution enterprises to announce green accounting report. France is one of the most advanced countries that adopted laws requiring companies to disclose environmental aspects in their annual reports (The NRE Act of 2001, the Grenelle I of 2009 and the Grenelle II of 2010). In other countries, narrative disclosures are mandated by regulatory agencies such as the Securities and Exchange Commission (SEC) in the United States. Some countries have preferred issuing recommendations and have delegated accounting bodies to regulate environmental disclosure. This is the case of Spanish environmental accounting standards (ICAC) issued in 2002, which obliged companies to provide a more comprehensive disclosure in their annual reports (Llena et al. 2007).

Environmental disclosure obligations derive from the commitments of nations to mitigate the negative impact of business activities on the environment, reduce global warming and climate change. Nations' engagement toward environmental protection is attested by the widespread participation in signing the United Nation Framework Convention on Climate Change (UNFCCC) in 1992, the Kyoto Protocol in 1997, and the Copenhagen Accord in 2009. Yet, the interest in environmental matters dates back to the Stockholm Declaration proposed by the United Nations Environment Programme in

1972 (Sohn 1973) and the Brundtland Report (United Nations 1987) that gave rise to environmental movements in several branches of business, politics, and society.

The European Union and its member states are extremely sensitive toward safeguarding the environment and have launched several initiatives to oblige companies to be more transparent on environmental issues. For example, the EU issued the Directive 2003/87/EC establishing an EU emissions trading system (EU ETS), the Accounts Modernization Directive 2003/51/EC, which requires a mandatory addition to the directors' report on relevant environment and employee matters using key performance indicators commencing on 2005, the Regulation 1013/2006 on waste transfer and the latest Directive 2013/34/EU on nonfinancial information that obliges large public entities to provide information on environmental aspects together with information on societal and governance aspects.

The shift from voluntary to mandatory reporting is attributed to the fact that companies were found to overemphasize their positive contribution to the environment while disregarding negative impacts in their communication. Research realized that environmental information was not genuine and of good quality. Green washing and impression management were quite relevant (Cho et al. 2014).

Regulation is held to increase the quality and volume of environmental disclosure. Demonstrating that regulation has a real positive impact on disclosure quality is albeit difficult. Some studies indicate that companies do not fully comply with the reporting regulations (Criado-Jiménez et al. 2007). However, regulation has undoubtedly a greater impact than any other form of soft rules as demonstrated by Fallan (2016) and Frost (2007), who describe how legally binding disclosure regulation has a stronger influence on environmental reporting compared to requirements and recommendations contained within standards. Yet, in some countries like China, it is still not clear what is the impact of national obligations on these matters (Situ and Tilt 2018).

Accounting Studies on Environmental Disclosure

According to Gray and Laughlin (2012), one of the early responses in academia to the environmental agenda is the so-called "green accounting" or "accounting for the environment" phenomenon. Appeared in the 1980s, after the work of Professor Peter Wood, this "green" approach drew heavily from the longer and more substantial social accounting literature, although its uptake implied – for some years – the abandonment of many wider social concerns (Owen et al. 1997). The main goal of green accounting was to measure, record, and disclose the impacts of corporate environmental activities on a company's financial status through a set of accounting systems. In other terms, it attempted to factor environmental costs into the financial results of operations. Unfortunately, green accounting lost its disruptive role in the 1990s, when environmental issues were integrated with social issues in stand-alone reports, separated from financial accounts.

The interest of accounting researchers in social and environmental reporting is demonstrated by the several special issues launched by academic journals (see, for example, *Accounting Forum* (1995, vol. 19, no. 2/3), *Accounting, Auditing & Accountability Journal* (1991, vol. 4, no. 3), *European Accounting Review* (2000, vol. 9, no. 1), *Accounting, Organization and Society* (1992, vol. 17, no. 5). In addition, new specialist journals in the field of accounting were launched like "*Social and Environmental Accountability Journal*" (the CSEAR house journal), "*Sustainability Accounting, Management and Policy Journal*" and "*Advances in Environmental Accounting and Management*."

A popular field of research is related to the level of disclosure and the identification of corporate and the country-specific determinants of environmental disclosure. Therefore, much effort has been devoted to find the best method for assessing firm's commitment to environmental aspects and transparency in communicating it. Several authors counted the number of words, sentences, or pages linked to environmental aspects in the annual report. After this, the relation between specific

variables and the amount of disclosures was tested (Deegan and Gordon 1996; Milne and Adler 1999; Neu et al. 1998). Clarkson et al. (2008) developed a scorecard in collaboration with an environmental disclosure expert to assess the firms' true environmental commitment and related environmental exposures. This scorecard – based on GRI guidelines – is held to be very comprehensive and complete; therefore, it has been applied in several empirical studies.

Another key topic of investigation is the relationship between environmental disclosure and environmental performance because authors hypothesized that higher disclosure does not mean greater care for the environment. Although, sometimes there are inconsistent results, it seems that better information is usually associated to more polluting industries (Clarkson et al. 2011; Fontana et al. 2015).

Several studies also discuss on the value-relevance of environmental disclosures by examining how investors evaluate company's environmental practices described in annual reports (Cormier and Magnan 2007), while other research focuses on theoretical explanations for environmental disclosure (i.e., the recur to signaling theory, legitimacy theory, and stakeholder theory).

Carbon Accounting Reporting

A quite recent trend within the field of environmental disclosure is carbon accounting: a means of measuring the direct and indirect emissions to the earth's biosphere of carbon dioxide and its equivalent gases from industrial activities. Carbon accounting does not have one unique definition, as it covers a wide range of activities related to the calculation, measurement, verification, reporting, etc. of carbon emissions at the international, national, company, and individual level.

Carbon accounting is discussed in political studies as well as among engineering studies. With the field of accounting and with reference to corporations, carbon accounting has been mainly supported by the work of accounting professors Jan Bebbington and Carlos Larrinaga (Bebbington and Larrinaga 2008; Larrinaga

2014), who consider carbon accounts as a basis for implementing actions to improve company performance in relation to the climate change impact. In fact, they consider three accounting implications of global climate change for companies: financial accounting of emission allowances under EU ETSs; accounting and reporting for climate change risks to corporate performance; and accounting and reporting for the uncertainty associated with climate change.

As described by Ascui (2014) in his review of carbon accounting in the social and environmental accounting literature, there are many empirical studies on the techniques used by companies to account for carbon emissions. These studies fall under the umbrella label of “environmental management accounting” and can be classified according to the approach used by companies for assessing business-related carbon emissions. Three main approaches can be identified. First, the bottom-up approach, also called process-based life cycle assessment (LCA), that focuses on gas emissions of a certain product or organization by analyzing every process in which emissions occur. This approach is used by the ISO 14040 standard on environmental management. Second, companies may use the top-down approach, also known as input–output model that allows identifying emissions sources and can help detect carbon emissions along long supply chains. Finally, there is the “hybrid” approach that combines both the process-based and input–output-based data models. On one hand, using the logic of the bottom-up approach companies can get more accurate data, while on the other hand, the top-down approach allows to account for emissions even where there is lack of process-based data.

Studies on environmental management accounting have strongly contributed to improve corporate practices as they have developed models for enterprises, being very practical oriented and less normative than traditional, social, and environmental accounting research. For example, Bradley et al. (2013) put forward a model for estimating emissions for small- and medium-sized enterprises, while Tsai et al. (2012) used a case study with a Taiwanese pulp

and paper company to integrate information about the cost of carbon and other externalities through Activity-Based Costing.

At the moment, the dominant and most widely used framework for carbon accounting is the Greenhouse Gas (GHG) Protocol, developed by the World Business Council for Sustainable Development and the World Resources Institute. Based on this GHG protocol, the Carbon Disclosure Project (CDP) has developed standards for reporting the results of carbon accounting to stakeholders. In the last 20 years, many voluntary frameworks and schemes have been developed to report the carbon emissions of businesses to investors or other stakeholders (see, for example, the guidelines of ISO 14031 on environmental performance evaluation). The aim of these standards is to increase transparency, favor comparability among companies and provide an evaluation tool for institutional investors and other stakeholders. However, neither these frameworks nor the obligation for carbon reporting under the Kyoto Protocol, EU ETS, and EU Integrated Pollution Prevention and Control Directive seem to have produced reports that are useful for investors. First Solomon et al. (2011) and then Haigh and Shapiro (2012) demonstrate that public climate change reporting is not useful for decisions of financial investors.

Finally, it has to be noted that also accounting bodies have tried to define reporting standards for carbon emissions. In 2005, there was the first attempt made by the International Accounting Standards Board (IASB) through its International Financial Reporting Interpretations Committee (IFRIC) to regulate the financial accounting of carbon allowances, but it failed. The IFRIC Interpretation no. 3 on Emission Rights was withdrawn after criticism by the European Union on how IASB was trying to accounting for emission rights from an environmental ethics standpoint.

Summary

Accounting for an organization's environmental impacts is fundamental in today's era of climate change and increasing amount of industrial

disasters causing severe negative consequences for the society and the environment. Capturing the effects of companies' environmental actions in their financial statements as green accounting is trying to do is yet not likely to happen. However, voluntary and mandatory disclosure of environmental aspects is developing through the issuance of standards and regulations.

In the 1990s, the rise of carbon accounting had made environmental aspects a key topic in the agenda of companies and nations. In the accounting literature, this caused an increasing emphasis on environmental, rather than social, accounting. However, green or carbon accounting cannot be considered in isolation as environmental aspect have critical social implications like negative impacts on the poorest sections of society, mainly in developing countries where people suffer from the consequences of climate change.

Ecological economics; Environmental and natural resource economics; Natural resource economics

Definition

Since 1960s environmental economics has become a subdiscipline of economics which integrates mainly welfare economics and growth. The root of this subdiscipline is the US Resource for the Future (RFF) research institute in year 1950s (Pearce 2002). The science economics is the discipline of the allocation of scarce resources. As a branch of economic, environmental economics is the practices and policies of environmental issues in an economic system to maintain the resources in the long run. This branch focuses on the cost and benefit analysis of the environmental and natural resources. Moreover, the methodology of the environmental economics is based on the positive and normative analysis by building economic models. The empirical literature on this area mainly focus on rationality and consistency test (Viscusi 2014).

Introduction

In the late 1960s, most developed countries began to concern about the natural environment and pollution. Economists also began to be interested in reasons and solutions for environmental problems (Maler 1974). Meanwhile, environmental degradation and pollution are perceived as crucial threats to economic development and economic growth (Munasinghe 1993). Environmental economics is a sub-discipline of economics that examines the impact of environmental problems, its subjects are often not included in mainstream economic theories. These issues are mainly based on environmental goods such as air and water that have utility but with no prices attached.

In parallel with the change in global environmental problems, environmental economy issues are also a rapidly changing field. Environmental economics focuses on the analysis and modeling of the cost of environmental damage (pollution, deforestation, deterioration of ecosystems,

climate change, etc.) generated directly or indirectly by economic activities and human behaviors, and the development of regional and global environmental policies. In the second half of the twentieth century, when environmental concerns began as a result of progress in environmental science and the development of tools and techniques in the study of environmental problems, scientific studies examining the relationship between environment and economics began to increase and gained importance.

The environment is a global concern today. In recent years, environmental economics integrates to the policy instruments or policy implications such as environmental taxation or UN Sustainable Development Goals (SDGs) (Pearce 2002). Environmental economics requires a multidimensional approach because of its interdisciplinary in nature. How economic units respond to environmental issues will depend largely on the behavior of these units in the face of scarcity.

Interlinkages Between the Economy and the Environment

Thus, environmental economics provides an analytical framework for examining the relationships between environment and economics. Moreover this field helps to identify environmental problems and search for the solutions. This field of economics aims to determine and analyze environmental policies to allocate natural resources more efficiently.

Hanley et al. (1997) show the interlinkages between the environment and the economy. In an economy, exchanges of goods, services, and production factors take place between production (supply side) and consumption (demand side) of the economy. The supply side extracts $E1$: energy and materials (such as oil and iron) as an input or production factors to transform into outputs (goods and services) to demand side of the economy and some which are waste products. The loops R_1 and R_2 indicate recycling of resources in production process. As a supplier of production

Environmental Economics, Fig. 1 The link between economy and the environment

E

process, the second role of environment is as a sink for waste materials. Thus, the natural resource provides three types of functions to an economy: natural resources based raw materials, serves as a sink to absorb or recycle the waste products, and amenity services to support human well-being (e.g., stabilization of the global climate) (Munasinghe 1993) (Fig. 1).

Environmental economics is mainly based on the theories and assumptions of neoclassical economics (Tietenberg and Lewis 2016). Neoclassical economics suggests economic value mainly dependent on social well-being (Hanley et al. 1997). T. Malthus, D. Ricardo, and J.S. Mill paved the way for the prediction that the limited nature of natural resources, in other words, would be scarce and, if natural resources were scarce, would lead to a decline in economic growth and consequently a reduction in social returns (Barnett and Morse 2011). Before the last quarter of the twentieth century, neoclassical economists laid the groundwork for the “marginal” concept and theories and the basis of methodological analysis of environmental economics. Pareto’s “Pareto efficiency” and A. Marshall and Pigou’s “Externality” and “Market Failure” studies contributed

to the foundations of environmental economics (Perman et al. 2013).

In early times, when economic activities were less than they are today, environmental problems were not considered as in today. Economists have sought methods to solve this market failure (Maler 1974). As in other fields of economics, environmental economics use models and quantitative techniques such as econometrics and also experimental economics to investigate the relationships between economics and environment. Moreover, game theory provides to address environmental issues. For example, the interaction between firms and policy makers over cuts in carbon dioxide emissions (Hanley et al. 1997). The economic cost and benefit analysis also provides tools and models to deal with the environmental issues.

Key Issues

Concepts such as carbon trading, congestion pricing, sustainable development, renewable energy trading, energy, depletable resources, ecosystem goods and services, and economics of pollution control are the key issues in this field of

economics (Batabyal and Nijkamp 2001). The study of environmental economics also covers market failure, economic incentives for environmental protection, transboundary pollution problems, pollution taxes, tradable pollution permits, economics of natural resources, renewable and nonrenewable resources economics, the economics of forestry, economic cost and benefit analysis, and the sustainable development. Tietenberg and Lewis (2016) indicate some key issues and questions in environmental economics:

- How does the science economics respond to scarcities?
- Many environmental problems involve a degree of uncertainty and risk. What is the role of political economy in controlling environmental problems?
- Can economic and political institutions as well as policy makers respond to these problems effectively?
- What is the role of economic and political system to sustain economic development and to preserve environmental sources for the future economic activity?

Summary

Environmental economics as a branch of economics considers the environmental and natural resources. Moreover, microeconomics examines the environmental economics in the light of the following terms and concepts including market failure, price discrimination, externalities, and public goods (Thampapillai and Ruth 2014).

Definition

The environment is regarded as the source from which living organisms extract all (natural) resources necessary for their survival and development. It can also be viewed as a medium within which ecological functions occur naturally. An environment can however be considered as natural environments, artificial environments, cultural environments, work environments, or digital environment (Abaza et al. 2004; Speight 2015). Based on the foregoing, an environmental impact can be said to be any type of environmental change, whether chemical, physical, or biological, which occurs as a result of human activities. Such activities are capable of causing direct or indirect effect

on the health of the population, economic and/or social activities, values of ecological resources, and biota (Hanania et al. 2020; Morgan 2012).

Introduction

The conflict between economic development and environmental protection is a very important issue to consider before starting any human activity that can cause negative environmental effects. Environmental impacts have become an issue of global concern since the 1960s in the attempt to facilitate an equilibrium between economic development and environmental protection. Industrialized countries with stable economies tend to favor environmental protection, while developing countries that try to compete in the global market tend to favor economic development (Pan et al. 2019). However, despite the concern, there seem to be generally less than adequate efforts to indeed protect the environment as may be evident from the frequency of environmental accidents even in the developed world affecting soil quality, water resources, and the human society at large (Morgan 2012; Pan et al. 2019). For example, in an industrial facility, the impact may extend beyond the direct exposure of workers at the facility and its immediate environments to emission of hazardous substances: energy production from the facility may stimulate changes in local climate from heating effects; industrial burning of fossil fuel can also increase climate change effect from CO₂ emission; mineral mining activities and siting of facility can cause soil contamination and damage of ecosystems; while emitted contaminants can infiltrate into local hydrology and food chain to ultimately affect the biotic population. The full range of the impacts of such activities can be extensive, complex, and highly unpredictable (Neff 1981; Moreira 1992).

Classification of Environmental Impact

Environmental impacts are primarily classified into direct, indirect, and cumulative impacts.

Direct Environmental Impacts

Direct impact exists when there is a direct interaction between an activity and any environmental component (Fig. 1) (Pan et al. 2019). This type of impact usually forms a cause and effect relationship thus is usually easy to detect and predict. A good example is the loss of biodiversity resulting from local deforestation activities or discharge of effluent from an industrial effluent treatment plant (ETP) into a community river that causes water toxins to increase thereby causing the water quality to decline (Tszmokawa and Hoban 1997). In another example, the use of fertilizers helps improve farm productivity by

supplying rapid nutrients to plants. However, leaching can result when there is excessive rainfall or irrigation that washes the nutrients such as nitrates and sulfur below the roots of the plant causing soil acidification and ground water contamination, and a direct environmental impact of fertilizer application on the soil (Wiederholt and Johnson 2017).

Indirect Environmental Impacts

This type of impact is sometimes referred to as secondary or chain impacts. Indirect impacts are not usually obvious and are more difficult to predict relative to direct impact (Fig. 1) (Sanchez

Source: Adapted from Tszmokawa & Hoban, 1997

Environmental Impact, Fig. 1 Types of environmental impacts

2006). It exists when a secondary or chain reaction is caused by an action (Pan et al. 2019). Such impact does not appear as a direct result of an activity, rather it occurs from a network of interactions or complex impact pathways. This type of impact is felt at a location far away from the cause or many years after the causal action had taken place. For example, ambient air SO_2 rise due to stack emissions may deposit on land as SO_4 and cause acidic soils (Tszmokawa and Hoban 1997). Also, in further consideration of environmental impacts of fertilizers, continuous use of fertilizers can cause nutrient accumulation which can be washed into water bodies in different location. When nutrients from a fertilized farm runoff into water bodies, they stimulate algae growth that depletes dissolved oxygen and causes eutrophication. This is an indirect environmental impact on water body in different location caused by fertilizer use on a farmland (Wiederholt and Johnson 2017).

Cumulative Impact

Cumulative impacts are changes caused by the interaction of an action with other past, present, and future actions (DEAT 2004). They typically result from either an additive, synergistic, or multiplicity effects of more than one action (Fig. 1). This type of impact can emanate from the incremental effect of an activity when it interacts with another similar or different effect from other activities that have been completed, are ongoing, or have to be completed in the future (Roudgarmi 2018). Such impact may constitute an insignificant impact separately but can become significant when combined with other impacts. A cumulative impact is additive when more than one impact that exhibits a similar character interacts to create a bigger impact. For example, runoff of nutrients from a fertilized farm may not be sufficient enough to significantly deplete dissolved oxygen in a water body but runoff from two or more fertilized farms can combine to cause significant reduction of oxygen to the extent that it becomes lethal to aquatic lives. Synergistic environmental impact takes place when more than one impact that exhibit different character interact to create

bigger impact. For example, in addition to depletion of amount of dissolved oxygen caused by runoff of nutrients from fertilized farm, oil spillage from exploration activity from a nearby oilfield will cause both chemical toxification as well as coating and smothering effect on aquatic lives. These effects will combine to form a devastating impact on the aquatic environment (Tszmokawa and Hoban 1997).

These three main classifications of environmental impacts may also be categorized based on the characteristics of the impacts into:

Positive and Negative Environmental Impact

An environmental impact is said to be positive if it supports the improvement of any environmental factor or parameter. For example, a project to relocate a population from a slum or shanty to a block of energy saving apartment or to develop a waste management system for a local community or to restore a river forest will create a positive environmental impact. On the other hand, where an activity results in a damage that deteriorates the quality of the environment or its components, a negative environmental impact is said to have taken place. Examples of negative environmental impacts include emission of industrial effluents into the atmosphere or water bodies without proper treatment and bush burning activities to prepare agricultural land for farming season (Pan et al. 2019). However, some activities can create both positive and negative environmental impacts. For example, the use of organic manure for farming can significantly improve soil nutritional composition and texture, but long-term use can cause accumulation of some nutrient and consequently loss of excess nutrient to the environment through erosion to water bodies and cause eutrophication (Wiederholt and Johnson 2017).

Local, Regional, and Strategic Environmental Impact

A local impact exists when an activity causes an environmental impact only within the place of the activity and does not extend to other regions. For example, a mining activity will usually cause a

local environmental impact. When the environmental impact spreads beyond its local surrounding to other regions, such as road construction, regional impact is said to have occurred (Pan et al. 2019). A strategic impact takes place when an activity causes an effect that transcends regional to national or international boundaries, such as the construction of Akosombo dam in Ghana on the Volta lake which stretches across six West African countries (Gyau-Boakye 2001; Pan et al. 2019).

Immediate, Medium, Long-Term and Cyclic Environmental Impact

When an action causes an effect to happen instantaneously or within a short time of the action, an immediate environmental impact is said to have occurred. For example, an immediate environmental impact is experienced by fish which die in a river due to the release of toxic compounds. A medium-term impact is represented in the effect of runoff of nutrients from a fertilized farm into a river which may not be noticeable until after a few years when there will be algae bloom that will cause eutrophication (Pan et al. 2019; Wiederholt and Johnson 2017). The bioaccumulation of contaminants (like methyl mercury) in the food chain is an example of long-term environmental impact because it takes time for these effects to appear, and when effects occur at regular time intervals, this is called a cyclic environmental impact (Pan et al. 2019; Biswas 2000).

Temporary and Permanent Environmental Impact

A temporary impact happens when an action causes a change that can be remediated within a short or medium term. An example of a temporary environmental impact is the leakage of oil (petroleum) to the coast, which is gradually absorbed by the environment over time. A permanent impact however takes place where the effect of an action will last for a long-term or remain permanent. Radiation is an example of a lasting environmental impact and its effects can take several years (Pan et al. 2019).

Reversible and Irreversible Environmental Impact

The combustion of tires results in pollution of the air which dissipates over time and the air returns to its original state, and this is an example of a reversible impact. Erosion resulting from excessive rain is an irreversible impact on the environment, since it takes thousands of years for the soil to regain its mass and fertility (Pan et al. 2019).

Summary

Environmental impact is any kind of alteration, whether beneficial or adverse, to any environmental component, physical, chemical or biological, which results from human activities. Industrialization brought about many environmental problems, thus the need to balance developmental goals with environmental protection became a common concern of the world. Environmental impacts of developmental project have now become an important consideration before project execution. Environmental impacts are generally classified into direct, indirect, and cumulative impact. However, depending on their characteristics, they can also be classified into positive and negative impacts; local, regional, and strategic impacts; immediate, medium, long-term and cyclic impacts, and temporary and permanent impacts; reversible and irreversible impacts.

EIA

Description

The premises of environmental impact assessment (EIA) lie in the Earth's limited environmental carrying capacity (Mebratu 1998; Meadows et al. 2005; Rockström et al. 2009; Steffen et al. 2015), the concept of sustainable development (WCED 1987), and the rise of public environmental awareness and concern (Jay et al. 2007). EIA first emerged as a formal process in the 1960s–1970s (Pope et al. 2004; Jay et al. 2007). Common applications of EIA include life cycle assessment (LCA) of product systems (ISO 14040: 2006; ISO 14044: 2006) and legislation-driven assessment of planned projects (Jay et al. 2007; Morgan 2012). EIA can take many forms in terms of the selection of environmental impact categories, impact indicators, and the spatiotemporal scope of impacts. EIA can serve as a preventive tool through which researchers, authorities, or decision-makers can better understand potential environmental impacts or identify current environmental hotspots within operations to improve environmental sustainability. Future EIA developments include quantifying positive environmental impacts (Sala et al. 2013; Dyllick and Rost 2017; Grönman et al. 2019), assessing environmental impacts and sustainability from a holistic, as opposed to reductionist, perspective (Ketola 2010; Laurent et al. 2012; Bjørn and

Hauschild 2013), developing understanding about microlevel impacts on macrolevel environmental sustainability (Dyllick and Muff 2016; Ryberg et al. 2018a; Ryberg et al. 2018b; Kühnen et al. 2019), and performing regionalized assessments of environmental impacts within LCA (Mutel et al. 2019).

Introduction/History

The term environmental impact assessment (EIA) has a dual meaning in contemporary literature. It can take the form of a broad umbrella concept that encompasses assessments of the environmental impacts of various activities, organizations, products, or people, and related assessment methods. Second, EIA is often understood as a legislation-driven stakeholder-participatory procedure through which the environmental impacts of proposed projects can be assessed. Historically, these two EIA concepts have evolved from environmental/sustainability assessment research and legislation.

Generally speaking, the scientific justification for EIA and its normative background lie in the absolute limits of the Earth's environmental carrying capacity. Economist Thomas Robert Malthus (1766–1834) presented a theory of environmental limits that highlighted how resource scarcity represents a limit to growth (Mebratu 1998). This concept was extended in 1972 when the Club of Rome acknowledged the planetary boundaries of economic growth in a report entitled “Limits to Growth” (Meadows et al. 2005). More recently, Rockström et al. (2009) and Steffen et al. (2015) quantified planetary boundaries and the safe operating space for humanity in their globally recognized research.

The early theories of limits to growth preceded the famous definition of sustainable development (Mebratu 1998) that was published in the United Nations World Commission on Environment and Development (WCED) report, which is also known as the Brundtland report, “Our Common Future” in 1987 (WCED 1987). The publication of the report represented a major political turning point (Mebratu 1998) and fueled a wide-scale

international debate. The more recent Sustainable Development Goals (SDGs) set by the United Nations established macrolevel environmental sustainability targets (UN 2015). Sustainable development is currently understood as a nested concept in which social and economic sustainability depend on environmental sustainability (Griggs et al. 2013).

The international standards of environmental management published by the International Organization for Standardization (ISO), in particular the standards on environmental life cycle assessment (LCA) of product systems, have widely contributed to how EIA is perceived. As a result of a participatory multistakeholder preparatory process, the first LCA standard ISO 14040, which covered the principles and framework of LCA, was published in 1997 (ISO 2019a), followed by a series of three further LCA standards (ISO 14040: 2006). ISO 14042, which was published in 2000, specifically addressed impact assessment (ISO 2019b) that is also known as life cycle impact assessment (LCIA) which is a mandatory phase of LCA (ISO 14040: 2006). Jolliet et al. (2004) first defined the overall framework of LCIA that presents the connections and available assessment methods and models between environmental pressures and impact categories (Jolliet et al. 2004; Veronesi et al. 2016). Currently, LCA is presented in ISO 14040 and ISO 14044, which were both published in 2006 (ISO 14040: 2006; ISO 14044: 2006). LCIA methods have actively developed since the 2000s (Hauschild et al. 2013; Mutel et al. 2019).

A specific and globally well-known application of EIA – to evaluate the potential environmental impacts of planned projects (such as industrial and agricultural activities, energy production, construction projects, waste management, traffic planning, or major changes to existing operations) – was originally designed in the late 1960s and early 1970s (Pope et al. 2004; Jay et al. 2007) in response to rising public environmental awareness and concern (Jay et al. 2007). This was fueled by the oil crisis and environmental disasters of the 1970s, for example, the Seveso accident in 1976. Principle 17 of the Rio Declaration on Environment and Development,

which was set at the United Nations Earth Summit in 1992, further contributed to the implementation of project-related EIA within national policies (UN 1992). Public demand for this specific branch of EIA is high, and the EIA process has been widely implemented in legislation within both developed and developing economies (Jay et al. 2007; Morgan 2012). This preventive EIA procedure facilitates the detection of potentially adverse environmental impacts of (major) projects, and authorities can withhold the permission to proceed in case of significant environmental risks (Jay et al. 2007). The EIA procedure includes hearings of potentially affected stakeholders (Glucker et al. 2013).

In parallel to the implementation of EIA in national policies, environmental issues were widely adopted within business in the 1990s (Ketola 2010). Historically, the consideration of the negative impacts that production processes have on the environment has shifted focus from reducing end-of-pipe emissions to improving efficiency throughout the supply chain and from a reductive to a preventive approach (Linnanen et al. 1997). Efficiency improvements typically reduce resource use and waste, thereby saving money for businesses and reducing negative environmental impacts. From the environmental sustainability management perspective, such efficiency improvements are business as usual (Ketola 2010). Emerging business approaches to EIA involve the identification of the positive environmental impacts of existing or future products or services (Dyllick and Roth 2017) and businesses' contribution to macroenvironmental sustainability (Dyllick and Muff 2016).

Environmental Impact Pathways

The causes of environmental impacts can be categorized in different ways. In general, the subjects that are of interest in EIAs are individuals/consumers, commercial or noncommercial organizations, processes, products, services, projects, events, countries, societies, and/or policies. A consumption-based approach or a production-based/regional approach can be used in EIA; for

example, while modeling national-level environmental impacts (UNEP 2010). Environmental impacts are caused both by resource extraction from the environment (input to a process), such as materials or energy, and by releases into the environment (output from a process), such as pollutant emissions (ISO 14040 2006; Verones et al. 2016).

EIA has the potential to depict impacts on a spatially and temporally wide range. Spatially, environmental impacts reach from local to global level (Jeswani et al. 2010). Some impacts are typical at a local level (e.g., water scarcity), while some are global (e.g., climate change). From the LCA perspective, a product system may cause environmental impacts globally, if the production processes of components, chemicals, energy, fuels, etc., are widely included in the system boundaries of the assessment. Similarly, the temporal scope of environmental impacts is broad, ranging from short-term to long-term impacts (Jeswani et al. 2010).

The EIA of projects considers the environmental impacts in the specific local context that the project is implemented in both the short and long term (Jeswani et al. 2010). In contrast, LCA is typically time and location independent (Jeswani et al. 2010). However, regionalization of the characterization of impacts in LCA has been actively developed during the past decade (Mutel et al. 2019) and environmental impacts are increasingly quantified based on specific local conditions rather than universal models.

Figure 1 depicts the causal impact pathway; that is, how environmental pressures/interventions (UNEP 2010), or using LCA terminology: flows across the boundaries of the system under assessment (ISO 14040 2006), impact the environment; and how potential impacts are typically assessed, especially within LCA.

Environmental impacts can be direct or indirect, and the impact pathway can form a complex network. Therefore, the environmental impacts can be modeled at different points of the impact pathway. The modeling approaches employed in LCA are midpoint and endpoint modeling. Areas of protection describe different aspects of the environment that are ultimately affected or

Environmental Impact Assessment, Fig. 1 Impact pathway (Jolliet et al. 2004; ISO 14040 2006; Finnveden et al. 2009; UNEP 2010)

damaged when impacts reach the endpoint, at which they can be assessed. Typically, areas of protection include the quality of the natural environment, natural resources, man-made environment, and human health (Jolliet et al. 2004; Finnveden et al. 2009). The sensitivity of the receiving environment (ecosystems, animal species, plants, people) that is exposed to the pressure may determine the severity of the impact. LCIA characterization models aim to cover the relevant cause-effect chains/impact pathways/fate and exposure and link the pressures to the environmental consequences (Frischknecht et al. 2016).

as freshwater ecotoxicity, marine ecotoxicity, and terrestrial ecotoxicity. Characterization factors are required to calculate the environmental impacts of a chosen category. Characterization factors define the extent of the impacts within the selected impact category due to inventory results in a defined unit. For example, according to IPCC (2007), the global warming potential impacts of greenhouse gas emissions can be calculated as carbon dioxide equivalents (CO₂eq) using the following characterization factors: CO₂ 1 kg_{CO₂eq}/kg_{CO₂}, methane 25 kg_{CO₂eq}/kg_{CH₄}, and nitrous oxide 298 kg_{CO₂eq}/kg_{N₂O}.

LCIA Methods

The principles for carrying out LCIA in LCA are standardized in the ISO 14040 standard. In this part of the LCA, potential environmental impacts are quantified based on the life cycle inventory (LCI) results. In the goal and scope definition of an LCA study, the LCIA method, impact methods, and categories are typically selected. An LCIA method represents a set of LCIA impact categories. Typical LCIA methods are, for example, CML, ILCD, Eco Indicator 99, ReCiPe, and TRACI. Some of the LCIA methods provide a wide range of impact categories, but some are more concentrated to a narrower perspective, such as toxic impacts. LCIA methods consist of impact category groups – for example, eutrophication and ecotoxicity – and these groups may consist of one or several impact categories, such

Environmental Impact Indicators

EIA provides both quantitative and qualitative information about environmental impacts, typically in the form of quantitative and qualitative indicators, respectively. For example, in LCA, environmental impacts are quantified, whereas qualitative environmental assessment may require the inclusion of stakeholder panels who are interviewed to elicit insights into the perceived environmental impacts (Jeswani et al. 2010). Environmental impact indicators are widely applied in corporate environmental reporting, marketing, environmental product declarations, product labeling, benchmarking, and environmental monitoring practices (Frischknecht et al. 2016).

Environmental indicators can be simple or more complex aggregate indicators (indices)

(Heink and Kowarik 2010). Quantitative indicators can further depict both the quantity and quality of the environment; for example, the impacts water extraction has on the water quantity available to other local users (water scarcity) or the impacts emissions have on water quality (water degradation) (ISO 14046 2014). The UNEP/SETAC Life Cycle Initiative has been developing a globally harmonized set of environmental impact category indicators (UNEP 2016).

When interpreting the significance of different environmental impacts, environmental impact indicators can optionally be normalized in LCA, which involves calculating the magnitude of the impact category indicator relative to reference information. Indicators can further optionally be weighted by converting, and possibly aggregating, indicator results across impacts. Impact categories may further be sorted and ranked (ISO 14044 2006). One approach to evaluating environmental impacts is through monetary valuation of different environmental impacts. For example, a review by Förster et al. (2019) demonstrated the cost-if-lost approach to highlighting the economic value of ecosystem services, an approach that may be useful in political decision-making processes. Environmental management standards define environmental performance indicators (EPIs) that provide information on how an organization manages its potentially adverse or beneficial impacts on the environment. The organization may select key performance indicators among the EPIs that are especially significant (ISO 14031 2013).

Footprints are typical environmental indicators that represent specific environmental impacts. They are used for reporting environmental performance (Ridoutt et al. 2016). Ridoutt et al. (2016) suggest that while LCIA impact categories eventually affect areas of protection predefined by the LCA community, footprint metrics address the specific areas of concern defined by the interests of stakeholders. A variety of approaches can be employed to quantify various footprint indicators, both LCA-based and other, and harmonization has been attempted (Ridoutt et al. 2016). Although their scope is narrow, the quantification of LCA-

based footprints shares features with the quantification of the more comprehensive environmental impact category indicators (Ridoutt et al. 2016). The two internationally standardized LCA-based footprints are carbon footprint (ISO 14067 2018) and water footprint (ISO 14046 2014). In the EU, the Commission has recommended the use of the LCA-based Product Environmental Footprint (PEF) methodology for assessing the broader environmental impacts of goods and services (2013/179/EU; JRC 2019), and respectively, the Organization Environmental Footprint (OEF) method for assessing impacts at an organization level (2013/179/EU).

Alongside reducing negative environmental impacts, there is an increasing interest in creating and measuring positive environmental impacts (Bjørn and Hauschild 2013), unburdening the environment (Kravanja and Čuček 2013), positive footprints (Dyllick and Muff 2016), net positivity (Dyllick and Rost 2017), and environmental handprints (Biemer et al. 2013; Grönman et al. 2019; Kühnen et al. 2019). One of the most recent positive metrics to emerge is the LCA-based carbon handprint, which compares the carbon footprint of the users of a novel product/service with that associated with the use of a baseline product or service (Grönman et al. 2019). The carbon handprint, which is created if the novel product reduces the users' carbon footprint in comparison to the baseline product, is assigned to the novel product/service and its provider (Grönman et al. 2019). Norris (2019) presented a similar general definition of handprint.

Future Directions

Some unresolved challenges remain in the field of EIA. Scientists have highlighted how, although sustainability and environmental management practices are becoming increasingly common in companies, the state of the environment is globally deteriorating (Dyllick and Muff 2016). Thus, there is an inherent need to measure truly effective microlevel (e.g., companies) contributions to macrolevel (regional/global) sustainability

(Dyllick and Muff 2016), or vice versa, translate global environmental challenges or targets, such as the SDGs, into measurable and assessable microlevel actions (Muff et al. 2017).

A sustainability management challenge that contributes to the disconnect between the microlevel and macrolevel environmental sustainability is that the EIA perspective tends to be excessively reductionist. LCA is, by default, a holistic approach in that it aims to expand the perspective from the environmental impacts of a single production process to the cradle-to-grave life cycle of a product, thus giving product designers and decision-makers information that can help avoid environmental problem-shifting between life cycle stages. However, the selection of environmental impact categories in LCA studies is often limited (Laurent et al. 2012). According to Ketola (2010) or Bjørn and Hauschild (2013), this represents a relative approach to environmental sustainability. In EIA, the focus has widely been on climate change impacts, although carbon footprint is deficient in representing environmental sustainability in terms of other environmental impacts (Laurent et al. 2012). Furthermore, Heijungs et al. (2014) stated that the environmental sustainability of isolated activities cannot be decided because absolute environmental limits can be established as planetary boundaries. That is, environmental sustainability is absolute and universal (Ketola 2010; Bjørn and Hauschild 2013). From the sustainability management perspective, a holistic approach to conducting EIA is required to avoid undesirable and unpredictable consequences and problem-shifting (Laurent et al. 2012).

Dyllick and Rost (2017) state that achieving true and universal product sustainability requires the assessment and optimization of the positive impacts of products. Earlier, Sala et al. (2013) concluded that LCA-based methodologies should be developed so that they can be used to enhance positive impacts while also fulfilling the traditional function of avoiding negative impacts. Recently, positive indicators have emerged, and this development is expected to continue. For example, area-of-concern-specific handprint indicators, in addition to the climate change-oriented

carbon handprint (Grönman et al. 2019), are likely to emerge. The positive approach can further help to understand businesses' contribution to macrolevel sustainability: Kühnen et al. (2019) developed a broader handprint methodology that considers the positive contribution businesses make to the SDGs. A future harmonization between different handprint approaches may be required, possibly through standardization.

Another recent attempt to decrease the gap between microlevel and macrolevel environmental sustainability concerned the introduction of an LCIA methodology that is linked to the planetary boundaries and the absolute sustainability approach (Ryberg et al. 2018a; Ryberg et al. 2018b). This PB-LCIA quantifies the safe operating space occupied by the activities under assessment. The method can aid companies to understand the impacts of their activities with reference to the planetary boundaries and, thereby, make more macroenvironmentally sound decisions (Ryberg et al. 2018a).

Abdoli et al. (2019) suggested a System-of-Systems (SoS) approach that was designed to offer a more comprehensive modeling of the environmental impacts of product systems through LCA. A SoS comprises the product system and the surrounding systems with which it interacts. The approach is intended to capture the rebound effects that are unforeseen in simple product system modeling. When rebound effects are included in LCA, the resulting total environmental impacts can be larger and more realistic than those impacts modeled directly from the product system (Abdoli et al. 2019).

Regionalized assessment of environmental impacts within LCA has the potential to increase the accuracy of LCA studies and reduce uncertainties in the quantified environmental impacts. Further development of regionalized EIA is expected. Challenges and development needs are related to regional data availability globally, lack of harmonization in determining and weighting the regionalized characterization factors of environmental impacts, insufficient quantification of uncertainty factors, and inconsistent metadata and data formats (Mutel et al. 2019). Furthermore,

new impact categories are continually being developed within LCA. For example, Maier et al. (2019) recently presented a conceptual framework for the assessment of global value chain biodiversity.

[Environmental and natural resources law](#)

Definition

Environmental law is the collection of laws, regulations, agreements, and common law that governs how humans interact with their environment (Sands and Peel 2012; Fracchia 2018). The purpose of environmental law is to protect the environment and create rules for how people can use natural resources. Environmental law involves a series of laws, policies, and procedures enforced by various agencies with the goal of protecting the environment. Environmental law often overlaps other laws to act as an extra layer of legal protection.

A related but distinct set of regulatory regimes, now strongly influenced by environmental legal

principles, focus on the management of specific natural resources, such as forests, minerals, or fisheries. Other areas, such as environmental impact assessment, may not fit neatly into either category, but are nonetheless important components of environmental law.

Customary international law is an important source of international environmental law. These are the norms and rules that countries follow as a matter of custom, and they are so prevalent that they bind all states in the world. When a principle becomes customary, law is not clear-cut, and many arguments are put forward by states not wishing to be bound. Examples of customary international law relevant to the environment include the duty to warn other states promptly about icons of an environmental nature and environmental damages to which another state or states may be exposed and Principle 21 of the Stockholm Declaration.

Numerous legally binding international agreements encompass a wide variety of issue areas, from terrestrial, marine, and atmospheric pollution through to wildlife and biodiversity protection. International environmental agreements are generally multilateral (or sometimes bilateral) treaties (a.k.a. convention, agreement, protocol, etc.). Protocols are subsidiary agreements built from a primary treaty. They exist in many areas of international law but are especially useful in the environmental field, where they may be used to regularly incorporate recent scientific knowledge. They also permit countries to reach agreement on a framework that would be contentious if every detail were to be agreed upon in advance. The most widely known protocol in international environmental law is the Kyoto Protocol, which followed from the United Nations Framework Convention on Climate Change.

Driven by fear of a disintegration of the internal market, concerns over portraying a less mercantile image of the EU, as well as the intention of safeguarding ecosystems and species under threat, a European environmental policy has thus gradually emerged (De Sadeleer 2014).

The broad category of environmental law may be broken down into a number of more specific regulatory subjects. While there is no single

agreed upon taxonomy, the core environmental law regimes address environmental pollution.

Five major laws are the Clean Air Act (CAA), the Clean Water Act (CWA), the Safe Drinking Water Act (SDWA), the Resource Conservation and Recovery Act (RCRA), and the Comprehensive Environmental Response, Compensation, and Liability Act/Superfund Amendments and Reauthorization Act (CERCLA/SARA).

A body of law intended to protect the environment, by regulating activities that cause pollution, such as fossil fuel emissions and the dumping of wastes; by prohibiting certain inconsistent uses of land designated as federal parkland; and by providing regimes of protection for endangered species.

The EU and its Member States have a wide range of laws to protect human health and the environment. The Commission (European Commission) is tasked with ensuring that Member States comply with these laws. Preventive measures are more effective and considerably cheaper than having to undo the damage caused by unsustainable practices. That's why the Commission promotes a proactive approach that begins with informal discussions and support to apply the EU rules.

The Seven Environmental Principles:

1. Nature knows best.
2. All forms of life are important.
3. Everything is connected to everything else.
4. Everything changes.
5. Everything must go somewhere.
6. Ours is a finite earth.
7. Nature is beautiful and we are stewards of God's creation.

The Evolution of EU Environmental Policy and Legislation

The evolution of EU environmental law and policy since the 1960s offers an interesting perspective from which to examine how the European project has remarkably expanded from the specific economic sphere of market integration to address new social challenges.

Overall, however, during the 1960s and early 1970s, it would still have been premature to think of a coherent set of EU environmental rules. Legal scholars tend to describe the EU's attitude to environmental protection at this stage as "incidental," "responsive," and "unarticulated" (Brinkhorst 1993, p. 9). The development of European policies in the environmental sector as well as in other areas concerning social welfare was regarded as a necessary element in the process of economic integration itself (Scott 1998, p. 10) and evolved primarily according to the contingent economic, political, and social circumstances (Hildebrand 2002).

Building upon these initial developments, the environmental policy of the EU started to become more consistent during the 1980s. The third EAP (1982–1986) contributed to shaping the direction of EU environmental legislation and policy at this stage. In particular, it emphasized prevention and a rigorous approach based on emissions reduction, rather than a quality-oriented approach, which would instead have left it to the Member States to determine the most cost-effective ways to achieve environmental quality objectives (Hanf 1997; Knill and Lenschow 1998; Knill and Duncan 2007).

Later the European Union (EU) has been buffeted by a range of crises since 2007, not least the economic and financial crisis. One potential victim of this economic malaise is environmental policy ambition. It is well-established that during economic crises, environmental policy (Burns et al. 2019) slips down the agenda with long-term consequences for environmental quality. The EU has sought to cast itself as a global environmental leader, but that leadership has in large part rested upon its ability to set ambitious policy goals at home. The future environmental policy trajectory and leadership of the EU may be under threat as the Union struggles to emerge from the economic crisis. This entry presents a comprehensive and robust analysis of all environmental policy outputs adopted by the EU over a 10-year period covering the crisis. This legislative analysis is supplemented by interviews with policy stakeholders. The article finds evidence of waning ambition over the period under analysis,

but a range of explanatory variables emerges from the interviews, which suggests that the diminution in EU environmental policy ambition is driven by a mix of factors and maybe likely to persist over the longer term.

In the 2008 Communication on Implementing Environmental Law, the European Commission identified specific strategies which tend to combine the enforcement powers of the Commission itself with an "ex ante approach" based primarily on the prevention of breaches. It focused particular attention on the design of legislation, involving a variety of actions and activities aiming to promote information, public consultation, and guidance for public authorities in the concrete application of EU environmental rules (European Commission 2008).

Interdisciplinary and cross-cutting nature of the climate change issue has acted as the main driver in focusing the EU's attention on the environmental- and climate-related aspects of energy, transport, and industrial policies. In this respect, the environmental dimension of EU energy policy is one of the most remarkable developments in the past few years (Schmitt and Schulze 2011).

Yet, the often difficult relationship between climate and energy policy and other environmental concerns points to one of the most pressing challenges that the EU is facing at present: reconciling the pursuit of competitive economic growth with the objectives of sustainability and environmental protection (Orlando 2013).

Yet, despite the shortcomings in realizing these ideals in practice, it is possible to share Ludwig Krämer's opinion that since the EU is also "the only region in the world which has publicly committed itself to try to reconcile economic growth, social concerns and environmental protection," it can, in this respect, offer a model to other countries or regions worldwide (Kramer 2007, p. 355).

About that the European Commission launched an ambitious 2020 strategy calling for a new era of sustainable, inclusive, and low carbon growth Communication from the Commission, Europe 2020, a strategy for smart, sustainable, and inclusive growth, 2020 final, 3 March, Brussels [Google Scholar]).

Summary

The work examines the fundamental aspects of environmental laws. After a definition with the reference subcategories, it summarizes the fundamental laws and the Seven Environmental Principles. It ends with the evolution of EU environmental policy and legislation since 1960 to nowadays.

Environmental Management Accounting

Nuwan Gunaratne
Department of Accounting, University of Sri Jayewardenepura, Nugegoda, Colombo, Sri Lanka

Synonyms

[Environmental cost accounting](#); [Environmental-related management accounting](#); [Sustainability management accounting](#)

Definition/Description

In a broad sense, environmental management accounting can be considered to identify, collect, record, analyze, and communicate physical and monetary environmental information for managers in internal decision-making (UNSDS

2001). The physical environmental management accounting provides information on the “use, flows and destinies of energy, water and materials (including wastes),” and monetary environmental management accounting supplies information about the “environment-related costs, earnings and savings” (International Federation of Accountants, IFAC 2005, p. 19). Although environmental management accounting’s primary function is to aid internal decision-making by supplying information for the corporate managers, this information can also be used by various other stakeholders, including regulators, investors, suppliers, and customers.

Introduction

Due to growing regulatory, social, and stakeholder pressures, organizations worldwide have started to follow various environmental management strategies and practices. In order to successfully implement these strategies and practices, organizations not only need to set sustainability goals but measure, evaluate, and communicate the progress toward the achievement of these goals regularly. As Schaltegger et al. (2017) suggest, it is essential to have accounting and management control systems to provide organizational decision-makers information for two purposes. First, they can act favorably toward environmental and sustainability initiatives if information about the undesirable ecological and social impacts are provided. Second, decision-makers and stakeholders can compare different environmental and sustainability alternatives by considering the sustainability impacts. Accordingly, various environmental and sustainability accounting practices, tools, and approaches, such as environmental management accounting, have emerged to support the businesses when implementing environmental and sustainability practices (Gunaratne and Lee 2019).

As environmental management accounting is an evolving discipline, it is challenging to find a universally accepted definition or boundaries for environmental management accounting (Burritt 2004; Burritt et al. 2002; IFAC 2005).

Nonetheless, the inadequate conceptualization, the notions, and tools of environmental management accounting have been used widely in research and practice (Schaltegger and Burritt 2010).

The aforementioned UNDS’s broad definition of environmental management accounting highlights two important features about the information supplied through the subject:

- (a) Environmental management accounting furnishes information about various ecological domains. Depending on the organization, these domains can range from raw materials, water, waste, energy, carbon, chemicals, and biodiversity.
- (b) Environmental management accounting information on these multiple domains can be expressed in physical and monetary terms (Burritt et al. 2002).

The first feature highlights that it is possible to have multiple environmental management accounting tools that focus on these numerous domains. The latter feature implies that environmental management accounting could be operated as physical environmental management accounting (PEMA) and monetary environmental management accounting (MEMA) systems. The physical environmental management accounting systems provide the information about the company activities’ impacts on the ecological environment expressed in various physical units as tons, cubic meters, liters, and joules. Conversely, the monetary environmental management accounting systems highlight the information about a company’s impacts on the economic system. These impacts can be expressed in financial measurement terms such as dollars or pounds. For instance, the cost of an environmental license fee or water or energy cost is expressed in monetized terms. Usually, these accounting systems can be considered further developments or extend traditional accounting systems’ scope (Burritt et al. 2002). In general, there is a connection between physical and monetary environmental management accounting systems. Commonly, the physical measures are identified or collected by

different departments, such as identifying energy consumption by the engineering department. When a financial value is assigned for these physical measurements, usually monetary environmental management accounting would occur (Gunaratne et al. 2014). However, this is not always the case. For instance, there can be several physical measurements for which a financial value is not assigned, or it is impossible to allocate an economic value. For example, a manufacturing company may record waste generation in tons without giving a monetary value. Although there are some tools and approaches for monetary value assignment, they will most likely have remained as physical measurements in an organization's book due to much skepticism. Similarly, a plantation company would keep the biodiversity records such as the number of flora and fauna species in their sites without assigning a monetary value. There can be some monetary environmental management accounting information in a similar vein that would not have a physical measurement, such as license fee and environmental fines.

Intending to provide a broad understanding of the different dimensions of environmental management accounting, Burritt et al. (2002), in their famous article entitled "Towards a Comprehensive Framework for Environmental Management Accounting," offers a framework. Accordingly, environmental management accounting information can be viewed along three dimensions:

- (a) Time frame (it can provide environmental information about past or future periods).
- (b) Nature of information (it can provide monetary or physical information).
- (c) Length of time frame (it can provide information about short or long terms).

- (d) Frequency (it can provide information on an ad hoc or routine basis).

Having combined these four dimensions, Burritt et al. (2002) offer the following comprehensive framework for environmental management accounting (refer Fig. 1).

The framework suggests that organizations can use a wide range of environmental management accounting tools to fall into different quadrants. Since environmental management accounting is designed to provide a broad set of principles, concepts, approaches, and techniques that support the management to implement environmental strategies successfully, it does not represent another environmental management tool (Christ and Burritt 2013; IFAC 2005). Therefore, Bennett et al. (2002) posit environmental management accounting as the interface between the internally focused management accounting and an organization's environmental strategies. More specifically, it has been suggested as a decision support tool to aid the implementation of corporate environmental management strategies (Schaltegger and Burritt 2010). Environmental management accounting decision support role is viewed broadly, including planning, decision-making, control, and performance evaluation (Passeti et al. 2014).

Environmental Management Accounting Tools

It is generally acknowledged that corporate sustainability is implemented with the application of sustainability management tools, including environmental management accounting (Horisch et al.

		Monetary		Physical	
		Short term	Long term	Short term	Long term
Past-oriented	Routine				
	Ad-hoc				
Future-oriented	Routine				
	Ad-hoc				

Environmental Management Accounting, Fig. 1 Comprehensive environmental management accounting framework. (Source: Burritt et al. (2002))

Environmental Management Accounting, Fig. 2 Domain-based classification of environmental management accounting tools. (Source: Gunarathne and Lee, 2021).

E

2015; Windolph et al. 2014b). Environmental management accounting tools denote “accounting instruments and systems that support companies to implement corporate environmental sustainability” (Horisch et al. 2015). Prior studies exhibit that organizations worldwide have adopted or applied a set of environmental management accounting tools (Christ and Burritt 2013; Ferreira et al. 2010; Gunarathne et al. 2021; Qian et al. 2018). Due to the evolving nature of environmental management accounting, the number of tools is expanding to introduce new tools or modification of existing management accounting tools to suit the organizational circumstances and requirements (Christ and Burritt 2013; Gunarathne et al. 2014; Parker 1997). Some of the commonly used environmental management accounting tools are listed below:

- Energy accounting.
- Waste and material flow cost accounting.
- Water management accounting.
- Biodiversity accounting.
- Life cycle costing.
- Eco-control.
- Environmental activity-based costing.
- Carbon management accounting.
- Environmental capital budgeting.
- Sustainability balanced scorecard.

Depending on the environmental domains these tools deal with, they can be categorized into two: (a) specific and (b) integrative/integrated

(refer Fig. 2). The specific environmental management accounting tools deal with a single ecological domain such as energy (energy accounting) and carbon (carbon management accounting). In contrast, the integrative tools need the information supplied by different specific environmental management accounting tools. For instance, the application of environmental capital budgeting or sustainability balanced scorecard requires the information provided by various domain tools such as energy accounting and material flow cost accounting.

Functional Roles of Environmental Management Accounting

These environmental management accounting tools and practices serve different managerial functions of an organization. Management accounting, a broad discipline in which environmental management accounting is rooted, considers several functional accounting roles. They are planning, decision-making, controlling, and performance evaluation functions (CIMA 2005; Drury 2009). According to Tillema (2005), these management accounting functions can be broadly divided into accountability (control or stewardship) and decision-making. Similarly, the following functional dimensions of environmental management accounting and their specific accounting tasks can be highlighted (see Table 1).

Environmental Management Accounting,
Table 1 Accounting tasks of environmental management accounting

Functional role	Accounting task
Decision-making	Decisions on cost and efficiency improvements
	Cost-volume-profit decisions such as break-even point and optimum production levels
	Pricing decisions
	Decisions on special one-off orders
	Make or buy decisions (insourcing and outsourcing decisions)
	Long-term capital investment decisions
	Replacement decisions
	Investment decisions such as mergers, acquisitions, and divestitures
	Expansion decisions (such as new products/services, equipment, processes, customers, and markets)
	Discontinuation decisions (such as products and services, customers, markets, and departments)
Control and stewardship	Budget preparation
	Statements for actual output analysis
	Variance analysis
	Setting performance targets and indicators
	Reporting of the achievement of actual results
	Comparison of actual against targets for performance evaluations
	Analysis and revision of targets Managing risk

Benefits of Environmental Management Accounting

Environmental management accounting benefits could be broadly categorized into three: compliance, eco-efficiency, and strategic position (IFAC 2005; Windolph et al. 2014a). The benefits of compliance could be seen in two ways. One way, it supports internally established environmental policies and benchmarks. Environmental management accounting is required to monitor

and track the success of these initiatives regularly. The other important way environmental management accounting benefits compliance is with external regulations and certifications/standards. For example, in many countries, a government authority (such as the Environmental Protection Agency in the USA and Australia and Central Environmental Authority in Sri Lanka) continuously supervises companies' environmental performance. In these circumstances, environmental management accounting is vital to ensure compliance with externally imposed regulations by providing the requisite information for the regulators. Sometimes, even in the absence of a business case, companies may have to implement environmental management and environmental management accounting. As stated by Fairchild (2008), traditionally, it is believed that costly investment in green production could be value reducing; hence there must be incentives for the organizations from the governments and other relevant regulators to invest in environmentally friendly activities. As suggested by Porter and van der Linde (1995), strict environmental regulators can encourage efficiency improvements and innovations within organizations and lead to competitive advantages.

Eco-efficiency denotes the concurrent improvements in organizational environmental performance and cost reduction and resource unitization activities. Adding a life cycle perspective to the definition of eco-efficiency, the World Business Council for Sustainable Development emphasizes that these cost reduction and resource efficiency activities should be followed throughout the life cycle of a product or service (Verfaillie 2000). According to Williamson et al. (2006), organizations can be motivated to adopt environmental management practices voluntarily for two reasons: (a) to achieve "the business case" and (b) to improve "business performance." The business case motive highlights the improvements in return to the shareholders and investors to become more attractive to the other stakeholder groups such as customers, supply chain partners, public, and employees. Business performance motive stresses cost reduction

and efficiency. Hence, eco-efficiency is viewed as a combined effect of both business case and business performance. Organizations cannot achieve cost reductions in energy, material, and water without proper accounting and control mechanisms like environmental management accounting. Most organizations focus on cost reduction, process improvements, and even the generation of additional revenue. Cost categorization frameworks in environmental management accounting allow identifying different environment costs for various purposes to aid decision-makers (see EPA 1995 and IFAC 2005 for more details). Hence accurate costing and pricing of products again contribute to the proper distribution of resources through demand and supply mechanism in the interest of the environment and broader society.

The strategic position resembles the use of environmental management and accounting to create a strategic value in the organization. In this way, environmental management accounting contributes to the marketing strategy to boost the company image. This further benefits company by way of attracting environmentally conscious customers, suppliers, and investors. Windolph et al. (2014a) refer to this aspect as motivation for market success. Further, Fairchild (2008) states that companies have an incentive to voluntarily invest in environmental policies since it creates a favorable impact on the company in the minds of “green-conscious” consumers and investors, strengthening the strategic position. Environmental management accounting provides reliable statistics and requisite information to devise an effective communication stagey to inform the stakeholders about an organization’s environmental practices and impacts.

Roadblocks to Environmental Management Accounting

Although there are many benefits, the implementation of environmental management accounting faces several limitations and challenges. Owing to these challenges, managers usually get incorrect,

omitted, or misread ecological information for decision-making. Accordingly, organizational decisions do not consider the full environmental impacts of the decisions being made (IFAC 2005; Burritt 2004).

There are several limitations in the implementation of environmental management accounting at the firm level. First, due to the limited management awareness, organizations do not place enough importance on identifying, collecting, processing, or considering environmental information in their organizations. Lack of management awareness and support do not allow environmental management accounting systems to develop in an organization. Second, due to the insufficient communication links between the accounting departments and other divisions that collect environmental information, managers do not get enough support in decision-making (Burritt 2004). Third, many organizations do not separately track and process environmental data due to the traditional bookkeeping systems. For instance, the cost of energy and waste management can be still considered as overheads. Due to this pooling of environmental costs in general overheads, decision-makers do not get the accurate information to lead to informed decisions. Finally, due to the highly internal oriented management practices, organizations do not seek to get the support of their value chain partners in their environmental management activities. For instance, organization do not get sufficient information about the environmental footprint of the raw material and other components from the suppliers. Accordingly, the decision-making process will lead to sub-optimal decisions as the entire life cycle environmental impacts of the resources will not be considered (Gunaratne and Lee 2019).

These challenges could arise due to organizational-specific reasons, inherent limitations of conventional management accounting practices, or as a combination of both. Irrespective of the underlying cause, scholars have often highlighted that environmental management accounting practices are not implemented comprehensively or systematically owing to these

reasons. Evidence shows that in many organizations, environmental management accounting practices have been adopted on an ad hoc basis in response to specific pressures. Therefore, organizational environmental management activities have not derived stakeholders' full support or given full benefits to the organization and society (Bartolomeo et al. 2000; Gunarathne and Lee 2015).

Summary

Environmental management accounting identifies, collects, records, analyzes, and communicates physical and monetary environmental information for various stakeholders. It is therefore not another environmental management tool but a broad set of accounting principles, techniques, and practices that supply information along four dimensions: (a) time frame (past or future), (b) nature of information (monetary or physical), (c) length of time frame (short or long terms), and (c) frequency (ad hoc or routine basis). There are specific or integrative environmental management accounting tools that will facilitate either decision-making or control and stewardship functions. By pursuing environmental management, accounting organizations can derive three broad types of benefits: ensuring compliance, achieving eco-efficiency, and strengthening strategic position. However, there can be various limitations that will inhibit the successful implementation of environmental management accounting.

Definition

The *Environmental Protection Agency (EPA)* of the United States was formed on July 9, 1970, by President Richard Nixon, and began operations on December 2, 1970. It is an autonomous administrative agency of the *United States Federal Government* responsible for all things related to environmental protection. The organization is headed by someone chosen by the President and confirmed by the Senate. This is not a cabinet division, even though the administrator receives a cabinet position. The agency is headquartered in Washington D.C. and has ten regional offices and 27 laboratories.

Key Functions

The EPA is primarily responsible for environmental assessment, research, and education. It enforces national standards on an assortment of environmental regulations, in discussion with governments at all levels including state, local, and tribal. As of 2020, the organization had nearly 13,000 employees – half of whom are engineers, scientists, and environmental protection specialists, while the rest consist of legal, public affairs, financial, and information technologists.

There are ten EPA regions throughout the United States. The central EPA office delegates monitoring and enforcement responsibility to these regional offices. The agency controls include enforcing fines, authorizations, and other actions. They likewise work with industries and all echelons of administration in a wide range of voluntary pollution deterrence programs and energy preservation efforts. While many public health and environmental groups feel positively about the agency, some critics believe that they commit government overextension by enhancing frivolous regulations on business and property owners.

History of the EPA

The impact of human activity on the environment has been a major concern since the mid-twentieth century. Rachel Carson's book in 1962, *Silent Spring*, educated the public about the damaging impact of the arbitrary use of pesticides on the environment. Minor bills were introduced in Congress leading to the *Resources and Conservation Act of 1959 (RCA)* and later served as a model for the *National Environmental Policy Act of 1969 (NEPA)*, which was signed into law on January 1, 1970. As a consequence, the *Council on Environmental Quality (CEQ)* was created, which was responsible for creating an environmental impact statement (EIS) which detailed the environmental impacts for all major federal actions on the environment.

The *Environmental Protection Agency (EPA)* was founded in 1970, and William Ruckelshaus was the agency's first administrator. It began overseeing pollution control programs and pesticide programs from the *United States Department of Agriculture* and the *United States Department of the Interior*. EPA began with 5,800 employees, and their budget for the first year was \$1.4 billion. The agency began as a technical assistance agency setting goals and standards and then gradually began operating more as a regulatory agency by proposing new acts and amendments, such as the

Clean Air Act (CWA), which recognized a nationwide agenda for tackling water quality, including mandatory pollution control benchmarks, in conjunction with the states. The *Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA)* was passed in 1972, requiring the EPA to examine the safety of all pesticides available in the market.

Other major Acts passed in the 1970s include the *Safe Drinking Water Act* in 1974, requiring the agency to develop mandatory federal standards in cooperation of state agencies for all public water systems, serving 90% of the US population. The Toxic Substances Control Act (TSCA) was passed in 1976 and was related to the manufacturing, labeling, and usage of commercial products. The agency gained the authority to create a national inventory listing of chemicals, test them, and regulate their production and use. The *Resource Conservation and Recovery Act (RCRA)* was approved in 1976 improving the earlier *Solid Waste Disposal Act* of 1965. In collaboration with states, it enabled the agency to develop regulations for solid and hazardous waste and setting national goals for waste disposal, energy conservation, waste reduction, and ensuring environmentally sound management of waste.

The 1980s saw the expansion and creation of more regulations by the organization. The *Comprehensive Environmental Response, Compensation, and Liability Act* (also identified as “Superfund” approved in 1980) authorized the agency to broaden their scope for those responsible for polluted by prior dangerous waste removal, and establishing a funding mechanism for assessment and cleanup. After the Chernobyl disaster in Ukraine in 1986, the EPA constructed an interagency group, including workers from the *Nuclear Regulatory Commission*, *National Oceanic and Atmospheric Administration*, and the *Department of Energy*, to oversee the situation. The *Emergency Planning and Community Right-to-Know Act* was enacted the same year, which enabled the agency to collect data on lethal chemicals and convey the information with the community. The following year, in 1987, the agency united with several

international organizations to form the *Montreal Protocol*, which was responsible for investigating the implications of stratospheric ozone depletion. The year 1990 saw the passage of the amendments of the *Clean Air Act* and newer methods by the EPA.

Laws and Programs

The EPA has principled enactment power for several federal environmental laws including the *Clean Air Act*, *Clean Water Act*, *Comprehensive Environmental Response, Compensation, and Liability Act*, *Emergency Planning and Community Right-to-Know Act*, *Federal Insecticide, Fungicide, and Rodenticide Act*, *Resource Conservation and Recovery Act*, *Safe Drinking Water Act*, *Toxic Substances Control Act*, and *Frank R. Lautenberg Chemical Safety for the 21st Century Act*. Additional laws where the EPA has a contributing role or provides assistance to other agencies are the following: *Engendered Species Act*, *Energy Independence and Security Act*, *Energy Policy Act*, *Federal Food, Drug, and Cosmetic Act*, *Food Quality Protection Act*, *National Environmental Policy Act*, *Oil Pollution Act*, and *Pollution Prevention Act*, among others.

The EPA has also started other key programs to support the prime missions. Some of the major central plans include the following: Air quality and radiation protection, Ambient standards (*National Ambient Air Quality Standards (NAAQS)*), *State Implementation Plans (SIPs)*), Stationary Air Pollution Source Standards (*National Emissions Standards for Hazardous Air Pollutants (NESHAPs)*), Motor source standards (*Motor Vehicle Emission and Fuel Standards*, and *Clean Fuel Vehicles*), Radiation Protection Program (*Radioactive Waste Management*, *Technologically Enhanced Naturally Occurring Radioactive Materials (TENORM) Program*, and *Radiation Standards for Air and Drinking Water Programs*), Science and Regulatory Standards (*National Pollutant Discharge Elimination System (NPDES)*, *Nonpoint Source*

Pollution Programs), Land, Waste, and Cleanup involving regulation of underground storage tanks, hazardous site cleanup, the Land Disposal Restrictions Program, the Oil Spill Prevention Program, and Chemicals and Toxics where the agency often reassesses all pesticides legally sold in the United States.

Other programs include the *EPA Safer Choice* program, branded earlier as *Design for the Environment (DfE)*, which helped customers and businesses identify and choose products with safer chemical materials, without forgoing quality or performance. Through the *Safer Detergents Stewardship Initiative (SDSI)*, environmental leaders who willingly commit to the use of safer surfactants are lauded. The *Energy Star* program is a voluntary program that encourages energy efficiency by an efficient usage of appliances, office equipment, lighting, home electronics, and more. The *Smart Growth Program* began in 1988 and helps communities protect healthiness and the ecosystem, create economic opportunities, and provide appealing and affordable neighborhoods for individuals across all socioeconomic levels. The *Brownfields Program* was passed in 2002 and provides grants and tools to local governments for the assessment, and revitalization, of brownfield lands. The *National Environmental Education Act* of 1990 helps to enhance the environmental literacy of citizens, while *Clean School Bus USA* seeks to alleviate children's exposure to diesel exhaust by eliminating excessive school bus idling. Finally, the agency has also established geographical programs for specific water resources such as the *Chesapeake Bay Program*, the *National Estuary Program*, and the *Gulf of Mexico Program*.

Global Presence of the EPA

EPA participates in several bilateral cooperative programs with many countries around the globe. This allows developing countries to benefit from the US leadership in building apt and successful environmental plans. As mandated by the

Antarctic Science, Tourism, and Conservation Act of 1996, regulations are in place to also assess the nongovernmental activities (including tourism) in this region. The agency also works with several countries in the Asia and the Pacific to safeguard global environment and public well-being. These include the following: Australia, China, Japan, Singapore, South Korea, and Vietnam. The work in Latin America and the Caribbean is done primarily in Brazil, Chile, Guatemala, Honduras, Costa Rica, and Peru and involves the provision of environmental tools and intelligence to aid governmental and nongovernmental organizations to lessen environmental ruin.

EPAs' work in Eurasia has lasted for over two decades and involves collaboration with Russia, Central Asia, the Caucasus, and Ukraine in the areas of environment, science, and technology. The United States association with Europe also goes back several years in maintaining economic and political alliances. They have jointly addressed environmental protection impacts on climate and worked on enhancing a purer environment around the globe. In the Middle East, the EPA's environmental collaboration focuses primarily on improving environmental governance, water pollution, water security, clean fuels and vehicles, and pollution prevention. Their work is mostly done in Morocco, Israel, and Saudi Arabia.

The three countries of North America – Canada, Mexico, and the United States – are involved in several collaborations to protect their shared environment. The EPA implements environmental contracts bilaterally and trilaterally with both partners. The United States-Mexico-Canada (USMCA) Free Trade Agreement and Environmental Cooperation Agreement (ECA) was operative on July 1, 2020, updating and replacing the *North American Free Trade Agreement (NAFTA)* and *North American Agreement on Environmental Cooperation (NAAEC)*, signed in 1994. Another major project is the *North American Development Bank (NADB)*, a binational institution established by the governments of the United States and Mexico to provide financing to

support environmental infrastructure projects. Finally, the EPA's environmental program in sub-Saharan Africa is dedicated to tackling the region's growing urban and industrial contamination concerns, such as air and water quality, electronics waste, and indoor air from cookstoves.

Summary

The EPA is beholden to the laws passed in Congress – appropriations statutes determine the amount of money that the agency can spend on each program. The agency, however, has the power of issuing regulations to various environmental situations and enforces the requirements, as long as a rationale for why a regulation is needed is provided. A major problem that persists even a half a century after the agency was founded is that the major programs regarding air, water, and waste and other programs remain unconnected, or placed in “silos,” and efforts are in place to have a stronger coordination between these divisions.

The agency has also focused its work on environmental justice. This has meant taking into account the neighborhoods where the underprivileged and minority populations live into special consideration when approving environmental legislation. Many of these concerns are local, and hence difficult to address by a federal agency, such as the EPA. Conflicting political ideologies in successive administrations can also be a factor in affecting the motivation for environmental enforcement. EPA is answerable to various constituencies, contends for resources, and tackles an eclectic range of damages to the environment. The agency is responsible for preventing and detecting environmental crimes, informing the public of environmental enforcement, and setting and monitoring standards of air and water pollution, hazardous wastes, and chemicals. From monitoring the fuel economy of automobiles to addressing climate change issues, the EPA has to address a myriad of challenges, including a lack of resources, and self-regulation of policies in order

to serve not only a country, but also all of humanity.

Environmental Report Following GBS Standard

Mara Del Baldo 

Department of Economics, Society and Politics,
University of Urbino Carlo Bo, Urbino, Italy

Synonyms

[Socio-environmental report](#); [Sustainability report](#)

Definition

Environmental reporting comprises the set of disclosure practices and tools pertaining to the effects of business interaction and the environment. It depends on environmental accounting, which encompasses specific sub-information systems that aim to measure, assess, and monitor environmental costs and performances that are often excluded from financial accounting.

In Italy, the environmental accountability model has been put forward by the GBS (Gruppo di Studio per il Bilancio Sociale), which is the primary association for scientific research on social and environmental reporting, and it serves as a national “standard setter.” Its social and sustainability reporting standard (GBS 2013) underlines the environmental impacts of organizations’ activities as regards the sustainable development objectives. The suggested environment communication system incorporates financial and non-financial information based on quantitative and qualitative data concerning an organization’s environmental performance in a specific period.

Introduction

The environment has been expressed as the natural physical space that encompasses the air, water, land, fauna, flora, and nonrenewable resources (minerals, fossil fuels, etc.) surrounding people and organizations (2001/453/EC). The European recommendation on the “recognition, measurement and disclosure of environmental issues” aimed to enhance the quality, transparency, and comparability of environmental information and yielded the earliest guidance for the disclosure of environmental information in the companies’ annual reports.

The growing awareness of the crucial role of environmental resources and their impact on the whole community at a local, regional, and international level necessitates an integration of environmental issues within every organization’s decision-making process (Baldarelli et al. 2017). Both doctrine and practice recognize the relevance of financial and nonfinancial environmental information in listed corporations’ annual reports and determined that financial types of sustainability disclosures (i.e., environmental management costs, allocations for potential liabilities and environmental investments) have market significance (O’Dwyer 2003; Moneva and Cuellar 2009). However, there is not a consolidated methodology practical for directly or indirectly determining the extent of environmental impact.

After the directive mentioned above, a key turning point in the regulatory evolution of financial reporting materialized with the directive 2003/51/EU – addressed to socio-environmental impacts. Moreover, the need to meliorate organizations’ environmental disclosure resulted in the enactment of the 2013/34/EU and the 2014/95/EU directives (NFRD). The latter is centered on the disclosure of non-financial and diversity information by public interest entities (PIE) – certain large undertakings and groups with more than 500 employees and that have either a balance sheet total of more than EUR 20 million or a net turnover of more than EUR 40 million – that are required to include a non-financial statement in their annual report. At present, the NFRD requires information about the environment, social and employee issues, human rights, and bribery and

corruption and underpins the assumption that non-financial information is indispensable for moving toward a sustainable global economy by combining long-term profitability with social justice and environmental protection. The non-financial declaration (the so-called NFD) should be incorporated in the annual report “to containing information to the extent necessary for an understanding of the undertaking’s development, performance, position and impact of organizations’ activity, relating to, as a minimum, environmental, social and employee matters, respect for human rights, anti-corruption and bribery matters” (EU 2014, p. 4). In providing this information, organizations that comply with the provision of the 2014 directive (entered into force in Italy in 2016) may be dependent on national frameworks (i.e., the GBS standard), or international ones (i.e., the OECD Guidelines for Multinational Enterprises, the Global Reporting Initiative and the Eco-Management and Audit Scheme).

In Italy, the GBS has been recommending non-financial disclosure for decades (Mio and Venturelli 2013). The GBS is a not-for-profit association that aims to promote scientific research on social reporting and diffusing corporate social responsibility implementation among private, public, and not-for-profit organizations. Since its establishment in 2001, the GBS has been appealing to institutions, scholars, practitioners, and professionals, including several Italian Universities, the National Order of Chartered and Professional Accountants (CNDCEC) and the National Association of Auditors (ASSIREVI). The GBS teams up with national and international organizations and encourages several research groups to spread knowledge through conferences, books, newsletters, and the website, which provide research documents and the standard for free.

Since the first standard’s publication (GBS 2001), a growing number of social and sustainability reports have been released by Italian organizations. The standard has been further refined and a renewed version was issued in 2013 (GBS 2013) to entail the environmental stakeholders in the undertaking of the calculation of value added and its distribution. In addition, research document No. 3 “Environmental Reporting and Value

Added” (GBS 2007) and No. 11 “Social and environmental reporting for corporate groups” (GBS 2010) have been published as the result of a thorough research on environmental accountability. Like many other processes and product standards, the GBS guidelines are an illustration of soft law, which is concerned with framing the problem and producing an operational and theoretical construct to support the transparency and comparability of social and environmental reporting (Baldarelli 2007).

The decision to issue the environmental reporting can also bring about the drafting of an independent environmental report, especially in companies operating in high environmental impact sectors (e.g., oil and gas). In this case “the qualitative and quantitative information should be transposed in a sequence that takes on the guise of a Chart of Environmental Accounts (CEA)” (GBS 2013, p. 55) that has been outlined to elaborate a comprehensive and autonomous environmental report (GBS 2013, pp. 61–68).

Key Issues

The GBS standard (GBS 2013) can be implemented by all companies called to/interested in realizing a socio-environmental report, regardless of the variety of environmental issues derived from the size and nature of the businesses’ activities. The standard is consistent to the international guidelines of Global Reporting Initiative, the most diffused environmental certifications (EMAS and ISO 14001) and other national and international standards.

The report includes: (1) the identity of the organization and its context; (2) the reclassification of financial accounting data and the estimation and distribution of value added; and (3) the socio-environmental report. It could be accompanied by additional sections and an appendix.

Information on socio-environmental perspectives should be succinctly introduced in the first part of the report by indicating the salient aspects of the socio-environmental context, followed by the explanation of the principles and values that prompt the mission and the main economic,

social, and environmental purposes. Strategies and policies should be described, including environmental management issues and prospects. The standard supports the notion of sustainable development and draws attention to the environmental impacts of business activities in two specific sub-sections of the report aiming to describe the social and environmental dimension, respectively.

Financial and non-financial information must be incorporated to make the overall organization’s situation comprehensible. The second section of the report must include environmental information of a financial nature (reclassification of financial accounting data) to estimate the value added produced by an organization including the revenues and costs (Table 1) of an environmental nature below presented.

The balance of the components mentioned above permits stakeholders to evaluate the impact of the management of environmental aspects on the outcomes of a fiscal year. The result is represented by the net global value added. Moreover, an elaborate analysis of these components must be given in the third section of the report, where data are used to calculate relevant indicators.

In the prospect dedicated to the analysis of the distributed value added, the environment is

depicted as an internal stakeholder. The statement should include the following categories of costs: payments to the Public Administration; payments to human resources; payment for liabilities/loans; remuneration of equity capital; donations; value dedicated to keep and implement the value equity; and the environment.

The third section of the report – referred to as the socio-environmental report – consists of a qualitative and quantitative description of the results realized by an organization, compared with its commitments, actions set in motion, and effects on stakeholders. Results are expressed by using metrics, comparisons, and narratives and are complemented by evidence and opinions. The socio-environmental report should permit various stakeholders to appraise what the organization has accomplished and gauge the organization’s environmental behavior. Moreover, it should allow the organization to engage stakeholders and sustain relationships with them.

To this end, the section should be an orderly series of information pertaining to the corporate identity statement (values, mission, strategies, and policies), qualitative/quantitative information, and indicators that aim to indicate the company’s environmental identity (see GBS 2013, Table 5.11), the direct environmental aspects (see GBS 2013, Table 5.12) and the indirect ones (see GBS 2013, Table 5.13).

The identity indicated the environmental policy, the management systems, and environmental certifications and studies (i.e., life cycle assessment), the adoption of the emission trading scheme, as well as details about any projects falling within the application of the environmental impact assessment. In addition, information about the governance structure and its orientation to adopt the best available technology in line with environmental evolution should be incorporated. In particular, the environmental identity should be presented by providing information on the production site, the technological plants and production processes, the environmental problems that the company faced, the eventual controversies and types of damage generated, the current (or planned) environmental policies and programs, and the monitoring activities. Data should be presented through readable information. For

Environmental Report Following GBS Standard,
Table 1 Costs and revenues pertaining to the management of environmental issues

Costs	Revenues
Raw materials consumption	Sales revenues
Cost of services	Increase of working orders pertaining to environmental product/ goods
Costs for leases	Other revenues/incomes related to the management of environmental issues
Cost of employees	Environmental contributions
Amortizations and depreciation of environmental assets	Extraordinary revenues/incomes
Allocation of funds for environmental risks	
Other allocations for the management of environmental issues	
Other environmental costs and charges	
Expenses for interest	
Extraordinary costs/ expenses	

Source: our elaboration from GBS (2013), p. 32

example, the information about the production site should summarize the production activities and locations, a plan of the areas that have been built and the green areas along with information about future plans.

Results should be consistent with the organizational dimension and the productive and operating dimension. Environmental information pertaining to water use, greenhouse gas emissions, and the use of materials should be grouped into three sections: (1) data on environmental costs; (2) account data on environmental costs, and (3) evaluation of environmental costs.

Quantitative data cover the production, consumption, and environmental impacts triggered by the corporate activity so as to monitor environmental performance. Environmental expenditures encompass the costs of initiatives set in motion to prevent, reduce, or repair damages to the environment (i.e., pollution, waste, noise, compromise of biodiversity), for example, disposal and avoidance of waste, protection of the environment, noise reduction, and protection of biodiversity and the landscape. In accounting terms, the environmental expenditures should keep up the characteristic of “specificity.” The balance among environmental revenues and costs highlights the environmental management impact. An elaborate analysis of environmental components includes data on air, soil, subsoil, and water emissions, aggregated by categories of pollutants and complemented by the measurement methodologies that have been implemented (i.e., direct measurements, sampling, etc.). Moreover, it should contain environmental performance indicators pertaining to environmental training and education activities, and the consumption of energy and non-recyclable materials.

Direct environmental aspects pertain to activities over which the organization has direct management control, including: the analysis of emissions, resource consumption, waste and liquid effluents, as well as corporate behaviors concerning the landscape (fauna, flora, aesthetic), ecosystem, and biodiversity. Waste generation should be indicated by typology, according to the European Waste Catalogue (EWC), and by distinguishing between municipal waste, hazardous and nonhazardous. The analysis is structured

into six elements (costs, financing, revenues and investments, matrix of the process/variables, analysis of resource consumption, emission and waste). For each resource, the quantity and consumption trend and the percentage of recycling should be indicated.

Indirect environmental aspects can derive from an organization’s interaction with external entities. Information accounts for environmental impacts that are indirectly connected to the production processes, including: the product life cycle, suppliers and their position in the value chain, carriers of auxiliary services, customers, and consumers.

Finally, the social-environmental report can incorporate additional sections dedicated to: stakeholders’ opinions; improvement of the report and assessments of appointed third parties. In fact, the report elicits dialogue and involvement of stakeholders whose comments and advice contribute to complete and improve future socio-environmental reports.

Future Directions

The environmental report has been designed as a voluntary tool that describes the relationships between companies and the environment and the effort they make to improve efficiency in the use of environmental resources. Companies that operate in sectors characterized by high environmental impact (i.e., the petrochemical and chemical industries) are among the first to publish environmental reporting, as well as companies belonging to the service sector (e.g., transport and telecommunications and waste management). The majority of multinationals have gradually made the environmental report part of their habitual practice, since it is a useful risk management tool and can be integrated with other corporate external communication instruments.

Data to be comprised within the environmental report are often already available in the company but, in most cases, must be retrieved and organized to support the decision-making process. The report should be understood as a dynamic tool that can evolve over time. Such evolution must be sought by both doctrine and practice, required

greater attention to educating students and the new generations because, despite an increasing attention to convey environmental performance, a sore point is represented by the authentic orientation to environmental sustainability (Gray et al. 2014).

Summary

The socio-environmental report recommended by the GBS contributes to improving the disclosure of information addressed to stakeholders, focusing on the environmental dimension and the related direct and indirect aspects. It provides a qualitative and quantitative description of the results accomplished by an organization, compared with its commitments, the actions undertaken, and the effects on stakeholders. The description of the environmental policy underlines the effort made to strategically deal with environmental problems and offer the organization an opportunity to critically rethink its business model and assess the coherence between the environmental approach and the declared corporate values.

Definition

Environmental responsibility is the idea that business organizations have an obligation to consider their impact on the natural environment. This obligation may be found in either the laws of the relevant jurisdiction(s) where they operate or in a broader moral obligation as an actor in society. The impact may be as a result of business consumables, production processes, or final outputs. Thus, businesses may have an environmental responsibility with respect to decisions about inputs, including sourcing, process choices, which may involve more or lesser impacts and discharges into the natural environment, and the environmental impacts of the specific goods or services they are supplying.

Environmental responsibilities are found in various hard and soft law instruments. Legal environmental responsibilities can be litigated in the courts, whereas other responsibilities may have different implications for the business, from membership in industry associations, voluntary accreditations, brand value, and social license.

Introduction

Historically, the effects of human activity on the natural environment have largely been ignored. Only after the Industrial Revolution did the effects become clear as skies over industrially active cities darken from the increased levels of smoke generated by coal powered factories and related processes. Polluted lakes and rivers became more common interfering with the use of adjoining lands and facilities. In the first instance, the courts were used to respond to these environmental issues as litigants invoked the laws of nuisance to address the issues.

This limited, court-based approach, despite the passing of rudimentary legislation in the 1850s, continued into the mid-twentieth century when significant pollution events drew public attention and significant concern and pressure to the issue. These events included an extended period of smog over the city of London, “The Great Smog,” a river catching fire in New York state

among others (Sheehy 2019a). At the present time, the phenomenon of global warming is widely acknowledged harmful environmental impact of human activity, the majority of which result of industrialization, its processes, and products. A range of responses have been developed including the idea of “environmental responsibility” in both public and private spheres.

The environmental responsibility is an idea that connects actions and their consequences in the context of business and the natural environment. It is a perspective that places demands on businesses to create not only economic value but to include social value by re-aligning their corporate objectives with stakeholder management and addressing environmental responsibility (Camilleri 2018). In its essence, environmental responsibility is the idea that a business that has a harmful impact on the natural environment (and they all do) has a responsibility to remedy or address that impact. Environmental responsibilities can be conceived of as being of two types: legal including contractual and moral.

Moral Environmental Responsibility

The moral argument for environmental responsibility is relatively straight forward. Where a party despoils something, that party is presumed to have a responsibility to remedy it. A fundamental problem in the case of the environment comes from its character as being generally available and belonging to no one – an area referred to historically as “the commons.” This characterization of the natural environment as a commons has two implications. First, as a result of the natural environment being a commons, any party has a right to use it as desired and no person has a right to demand another to refrain from using and despoiling it. Second, while in preindustrial contexts, the commons could be used by all and a general set of norm constrained misuse and excessive use, the rise of capitalism, and industrialization changed the extent of the impact as well as the underlying institutions of society itself. The change of norms from using the commons for sustenance living to using them to maximize individual profits led to

over exploitation of commons and destruction of the natural environment (Cox 1985; Crowe 1969; Hardin, 1968; Ostrom 2008).

Where the benefit as well as the costs was equally shared, a norm of fairness was in operation and there was little need to impose a distinct environmental responsibility to remedy for despoilation. Once that model was upturned by industrialization and capitalism, and exploitation of nature done at a scale where despoilation deprived others of benefit or imposed costs on them, a reconsideration of the norms underpinning unrestricted approach to the commons is required. In other words, the moral argument comes from the unequal destruction and benefit derived from the exploitation of the natural environment. Thus, where a party has benefited from exploitation of the natural environment, a responsibility exists to remedy that harm for the benefit of those who have lost that resource.

This moral argument has been institutionalized in ideas such as “social license,” “corporate social responsibility,” “corporate citizenship,” and “corporate environmentalism” (Sheehy 2012, 2015; Sheehy and Farneti 2021). These arguments have been advanced by various parties and been used to influence management decisions. To a significant degree, this argument has been institutionalized by making the business case for implementing technologies to reduce environmental impacts. Basically, the business case is creating an argument for business decision-makers demonstrating that investing in environmental improvements will benefit the financial performance of the business. Many commentators argue that companies that practiced social and environmental responsibility did well by doing good, in the long run (Camilleri 2017). In other words, the environmental norm has been changed and subordinated to for-profit norms of business. Nevertheless, there is still strength in the moral argument as expressed in the term social license. Activities such as boycotts, condemnation on social media, as well as positive engagement in environmentally focused programs are reactions at least to some degree to the moral argument.

Legal Environmental Responsibility

The legal argument for environmental responsibility is developed out of a category of law referred to as tort law. That category of law allows parties to seek remedies for noncriminal harms including pollution. A basic principle of law is a right not be interfered with and a correlative duty or obligation not to interfere with others. Following from this principle, where an industrial activity spoiled the environment and interfered with the rights of others, the law placed a duty to compensate the harmed party. The general approach of tort law did not differentiate between environmental harms and any other harm. Subsequently, there have been both legislative and soft law developments.

Legislated Environmental Responsibility

The development of environmental law in the contemporary era can be traced back to the initial legislation in the UK, the *Smoke Nuisance Abatement (Metropolis) Act 1853*. Subsequent legislation and reforms have continued there and elsewhere to the present day. The result of this legislation was to replace the initial legal approach, which provided remedies to parties harmed by pollution and other industrial activities on a case-by-case basis with a legislative, society wide approach to address the mounting environmental issues.

As a result, legislation has been passed in many jurisdictions to address various types of pollution such as air quality, water quality, waste management, contaminant clean-up, and general chemical safety. These legislative instruments often create a regulatory organization with rights and duties with respect to monitoring, standard setting, and prosecution of breaches of duties. The result is that prosecution of environmental harms does not depend on the initiative and resources of private individuals; rather, the burden has been shifted to government. The problem remains, however, that law provides a remedy only after an environmental harm has been done.

Soft Law Environmental Responsibility

At the level of international law, a set of three broad principles has emerged. These are the principles of prevention, polluter pays, and the precautionary principle (De Sadeleer 2002; Sheehy 2019a). The first principle requires proactive efforts to prevent pollution in the first place by use of appropriate technology, processes, and safeguards to ensure a minimal standard of environmental protection occurs. The second principle acknowledges that pollution will occur, that the costs do not simply disappear into the atmosphere but must be paid by someone. The principle requires the business that creates pollution and presumably benefits from that creation pays the cost rather than off-loading to other individuals or society at large. The final principle, the precautionary principle, takes a different approach. It is based on an acknowledgment that some aspects of the environment are critical, irreparable, and/or inherently worthy of preservation, and further that it would be unwise to risk harm to those aspects. Accordingly, rather than taking a remedial or repayment approach, the wiser approach is to avoid the harm by taking a precautionary approach.

In their essence, these principles prescribe a set of approaches to environmental responsibility. As international principles, they have been accepted as just to all and necessary to protect the environment from the problem of industrial pollution. They have been enacted not only in the international legal system but also in many other regional and national legal systems.

A major method of developing, participating, and implementing environmental responsibility is through various private soft law initiatives (Abbott and Snidal 2000). These soft law initiatives are found in many industries and put forth by several actors. Perhaps most well-known, the ISO1400 standard, provides a template for business organizations to manage their environmental impact. Other well-known standards include the standards of the Forestry Stewardship Council and the Marine Stewardship Council. These standards, often codified, are adopted by business organizations on either the business case as

mentioned above or purely moral grounds or some combination of the two.

As soft law, these standards of environmental responsibility, often codified, do not have the force of hard law (Sheehy 2019b). There is no court to which one can bring offenders who breach these standards. Nevertheless, they are useful in directing, at least to some degree, decision-making within organizations. As no business is wholly stand alone, some of these standards are implemented through contractual arrangements in supply chains (Rahdari et al. 2020). For example, a large retailer may demand that all wood used in the manufacture of its products be sustainably sourced as certified by compliance with the Forestry Stewardship Council standards (Vandenberg 2006).

Economic Rejection of Environmental Responsibility

Economics as a discipline identifies no responsibility or duty. Rather, it uses categories of costs and benefits. In economic terms, pollution is simply a cost. As analyzed by Ronald Coase, these social costs are merely matters of property rights, which ought to be traded by private parties to pursue their own private interests (Coase 1960). The solution to pollution – that is, environmental responsibility – in an economic framework is simply expanding property rights such that a right to cleaner environment could be litigated.

This economic approach has been a major obstacle to other approaches to environmental responsibility. From an economic perspective, destruction of the environment is a cost, which only needs to be addressed by payment rather than ecological preservation. Where a party has property rights over something, which may have an environmental impact, there is no moral obligation to preserve or refrain from maximum exploitation of the environment. Indeed, there is an economic incentive to destroy it to maximize profit. Further, as economics holds that there are always commensurate goods, there is no reason to refrain from destruction of the natural environment. As a result, economic norms encourage

environmental destruction in the absence of costs imposed by law on that destruction.

Summary

Environmental responsibility is an idea based on conceptions of fairness. In a nutshell, the idea is that business organizations that benefit from the exploitation of the natural environment have duty to minimize their environmental impact and an obligation to compensate society at large for their negative impacts. These responsibilities are founded in both moral and legal norms. The legal norms are found in national, international, and private soft law systems. At the international level, the norms are prevention, polluter pays, and the precautionary principle. Economics opposes any responsibility and instead prefers financial incentives and penalties.

Environmental Transparency

Daniela Lud
Faculty of Communication and Environment,
Rhine-Waal University of Applied Sciences,
Kamp-Lintfort, Germany

Synonyms

[Environmental accountability](#) (both with a different connotation or meaning; see below); [Environmental disclosure](#)

Definition

Environmental transparency concerns the willingness of companies or organizations to share information on environmental performance with people who are interested (Wong et al. 2021). The International Monetary Fund (IMF) defines environmental transparency as “a process by which information about existing conditions, decisions and actions is made accessible, visible and understandable” (IMF 1998, p. v). Thus, environmental transparency refers to communication of information about the environmental impacts of a company’s activity. Environmental transparency also covers aspects of governance and control of companies or organizations, both from an inside and outside perspective (e.g., the perspective of the management of a company and the perspective of citizens). Environmental transparency can be defined as “the degree to which information is available to outsiders that enables them to have informed voice in decisions and/or to assess decisions made by insiders” (Florini 2007, p. 5). The idea of governance and control from several perspectives is also reflected in the definition of environmental transparency by Gupta and Mason (2014), who define the term as “disclosure of information intended to evaluate and/or steer behavior” (Gupta and Mason 2014, p. 357).

The term environmental disclosure is similar and sometimes used interchangeably, but disclosure has a slightly different connotation compared to transparency: It reflects a company’s responsibility with regard to activities having a negative impact on the environment, in response to a legal requirement to inform clients, shareholders, or other actors.

Another term related to environmental transparency is environmental accountability. Environmental accountability implies that companies take responsibility for their actions, the environmental impact, and the consequences thereof (Suadiye 2021).

Environmental Transparency: Trends and Concepts

Environmental transparency is strongly linked to the right of the public, to be informed about environmental impacts of companies that might affect citizens (Florini 2007). In the 1980s, industrial accidents like the Bhopal disaster in 1984 led to new legislation, for example, in the USA, where the Emergency Planning and Community Right to Know Act was passed in 1986 (Durant 2017). This Act was different from previous legislation in the sense that it represents an environmental transparency approach: Through the Act it was mandatory for companies to disclose emission data, information about toxic substances released had to be filed in the Toxics Release Inventory. Sharing of emission data resulted in a significant reduction of emissions and initiated better environmental performance of companies (Ramkumar and Petkova 2007). Since then, many countries have introduced similar legislation providing citizens with a right to know and access to environmental information (Fox 2007). Such an approach is also referred to as regulation by revelation (Durant 2017; Ramkumar and Petkova 2007). More recently, climate change, environmental pollution, and the current use of natural resources call for sustainable forms of consumption and production. Mostly, production and consumption of goods are associated with negative impacts on the environment, e.g., waste production, pollution of air, water, and soil, and emissions of greenhouse gases. Therefore, companies take steps toward more sustainable production, as business operations, which significantly harm the environment or deplete natural resources, are not sustainable (Suadiye 2021). In other words, environmental transparency can make a contribution to transforming economy toward sustainability.

To protect healthy living environments in a better way, governments and authorities provide governance by promoting the open availability of information. This way they create opportunities for more participation and access to information regarding the quality of the environment. The idea of environmental governance is that access to

information on the one hand enables people to participate in informed decisions, and on the other hand motivates companies to improve environmental performance of their operations (Durant 2017).

Environmental transparency is based on the willingness of companies to share information about environmental management and environmental performance. Among some scientists (e.g., Wong et al. 2021), there is considerable confidence that environmental transparency can achieve more accountability, better governance, and thereby reduce environmental risks. Companies adopt environmental accountability practice, i.e., an attitude of acknowledging responsibility for operations and their environmental consequences (Darbishire 2010; Wong et al. 2021). However, practice shows that there is no clear-cut relationship between transparency and accountability (Nadesan 2011). There are several reasons for this. One reason is that companies often do not report directly to citizens (Nadesan 2011). Furthermore, information might not be disclosed clearly or in a suitable format for critical evaluation. Also, if information about environmental releases does not result into sanctions, e.g., due to a lack of capacity at authorities, transparency does not directly result in accountability (Fox 2007). This means that more efforts are needed to slow and turn the global environmental decline, citizens need to take more responsibility for environmental governance, e.g., as consumers (Axelrod and VanDeveer 2019).

Governance in the context of sustainable development puts a focus on accountability, transparency, participation, and access to justice (Bond et al. 2013). Regarding the aspect of financial accounting, financial information is required about environmental economic impacts. Examples for financial impacts of environmental issues caused by the company's activities include environmental fees or fines, costs of site closure in case a site needs to be abandoned, decreased value of production installations due to pollution, and liabilities caused by pollution or emissions (Schaltegger and Burrit 2000). Relevant information about environmental economic impacts needs to be described and quantified financially, because

Environmental Transparency,

Fig. 1 Stakeholders and target groups of environmental transparency (see Nadesan 2011; Schaltegger and Burrit 2000; Wong et al. 2021)

E

costs (for fees, site closure, or liabilities) can be considerable. So, disclosure of environmental economic impacts helps to create transparency and accountability in relationships with different stakeholders such as shareholders, investors, non-governmental organizations (NGOs), and citizens (Schaltegger and Burrit 2000). Figure 1 gives an overview of different stakeholders, which are target groups of environmental transparency.

Voluntary Versus Mandatory Regimes of Environmental Transparency

Generally, there are two types of transparency regimes. They can be either voluntary or mandatory (Durant 2017; Nadesan 2011). Voluntary regimes of environmental transparency are set up, used, and monitored by actors of the private sector (e.g., industries or NGO), and are followed on a voluntary basis. Examples for such voluntary transparency codes are guidelines developed by the Global Reporting Initiative (GRI) or ISO 14001 standards for environmental management (Durant 2017; GRI 2022).

Mandatory regimes of environmental transparency are binding and enforced by authorities based on existing laws and regulations. There are numerous environmental transparency codes or regulations, which entail a right to know (i.e., a right of the public to be informed about hazardous substances or environmental releases of companies or organizations that might affect people). Examples like the Basel Convention on the

control of transboundary movement of waste or the Emergency Planning and Community Right-to-Know Act mentioned earlier (Durant 2017; Fox 2007; Ramkumar and Petkova 2007). In a similar way, the European Air Quality Directive and Water Framework Directive, both have reporting requirements and therefore can also be regarded as right-to-know legislation (Makuch and Pereira 2012).

The disclosure of information can be “soft,” i.e., informal or “hard,” i.e., more formal (Wong et al. 2016). The latter forms of disclosure comprise disclosures linked to environmental management systems (e.g., ISO 14001), disclosures linked to certification or related to environmental performance indicators, and such related to capital spending. “Soft” disclosures are releases of information in a less formal way, e.g., on a website or via trainings (Wong et al. 2016).

Environmental Transparency in International Legislation and Guidance Documents

Some authors see an increased momentum for transparency and describe the development of an expanding number of international laws and regulations about environmental transparency as a “transparency turn” (Gupta and Mason 2014). According to Nadesan (2011), NGOs and activists played an important role through their calls for more transparency on both social (e.g., related to labor rights) and environmental transparency.

Early milestones of international legislation include the 1969 US-EPA National Environmental Policy Act and the 1976 US Toxic Substances Control Act. More recently, in 1998, the Aarhus Convention on access to information, public participation in decision-making, and access to justice in environmental matters was signed. The focus of this convention is on the interaction between the public and authorities. It jointly addresses environmental and human rights and provides a procedure for government transparency, accountability, and environmental protection (Bond et al. 2013; Wolf 2013). In 2000, the Cartagena Protocol on Biosafety was set up to protect biodiversity from genetically modified organisms, describing procedures of advance informed agreement and provision of information. This Protocol is similar to other right-to-know and informed consent legislation like the Basel Convention and the Rotterdam Convention, which aim at better governance of risks of safe transboundary movement of hazardous chemicals through more transparency and more right to know of governmental institutions, NGOs, or citizens. Furthermore, the European Chemicals Policy on Registration, Evaluation, Authorization, and Restriction of Chemicals, REACH, has a strong transparency component, as it gives companies the responsibility to share information on chemicals produced and marketed in the EU. These developments underline that it is important for stakeholders to receive relevant nonfinancial information (Bond et al. 2013). The Non-Financial Reporting Directive (NFRD, Directive 2014/95/EU) describes the regulations regarding disclosure of nonfinancial environmental and social information, which needs to be provided by large companies. Social information comprises work, human rights, corruption as well as diversity-related information.

Private labels also reflect disclosure and the right to know of consumers to be able to take informed decisions (Gupta and Mason 2014). Voluntary reporting activities of companies, e.g., the Global Reporting Initiative (GRI), which was launched in 1997, has produced the first set of integrated standards for sustainability reporting (Suadiye 2021) and thereby provided

important guidance for the practical implementation.

Environmental policy evaluation shows that regulation through transparency works in many cases (Durant 2017; Wisner et al. 2010). However, the evaluation yields mixed results, with respect to normative (i.e., pertaining to the right of the public to know about impacts), procedural (i.e., regarding procedural processes and participation), and substantive effects (i.e., concerning the actual reduction of emissions) of transparency (Durant 2017; Gupta and Mason 2014). This is further explained in the following paragraph.

Benefits and Challenges of Environmental Transparency

Environmental transparency is expected to motivate companies to improve their environmental performance and to make the change to a more sustainable production. Looking at scientific literature, the main body of research discusses environmental transparency positively (Gupta and Mason 2014; Wehmeier and Raaz 2012). Looking at the connotations and the way how environmental transparency is described, positive connotations very clearly outweigh negative ones (Wehmeier and Raaz 2012) and support the general idea that organizations or companies should be more transparent, but also indicate a lack of critical reflection of the concept. Positive effects described are organizational benefits, higher level of trust, more ethical behavior, better reputation, legitimacy, higher accountability, better understanding, and compliance (Wehmeier and Raaz 2012). Marshall et al. (2011), for example, found that high-polluter-industry companies tend to share more information voluntarily and suspect that this is due to pressure of NGOs and citizens. The negative aspects mentioned in the study were far less frequent: conflicting with other demands, protection of business secrets, disadvantage to competitors, and loss of control over information.

Wisner et al. (2010) found that good environmental performance often is related to good financial performance. They could show that environmental performance is positively

associated with environmental proactivity. In addition, the study revealed that those companies, which score better in environmental disclosure, also score better in environmental performance. On a societal level, more information is considered to foster more informed decisions of citizens, which is supposedly linked to more democracy (Christensen and Cheney 2015).

However, evaluating different forms of access to information by citizens or NGOs might not be easy (Hillebrandt 2021). In practice, environmental transparency effects show successes and setbacks. Challenges are due to the (partly voluntary) nature of environmental transparency activities (Durant 2017). Companies or organizations often are reluctant to change and disclosure might not always be desired within companies. One example illustrating the challenges of environmental transparency with respect to normative, procedural, and substantive effects is a group of chemicals called the poly- and perfluoroalkyl substances (PFAS). PFAS are chemicals used in a wide range of consumer products such as fast-food packaging, firefighting foams, or home textiles (Eschauzier et al. 2012). PFAS are present as contaminants in the surroundings of sites where companies produced these substances (Wickham and Shriver 2021). With regard to the normative effects of transparency, for PFAS there are indications that the right to know was not granted adequately: Companies were found to withhold information for strategic reasons (Richter et al. 2018), resulting in a considerable asymmetry of information between companies, authorities, and citizens. On a procedural level, it is not straightforward for agencies and authorities to hold companies accountable, e.g., if the substances are not sufficiently regulated in a country (with advisory values rather than binding limit values, Wickham and Shriver 2021). In addition, reaching substantive effects in the case of PFAS is difficult as the substances are technically hard to deal with, among others due to their persistence and a lack of published data (Eschauzier et al. 2012; Wickham and Shriver 2021). Other general reasons for setbacks are a lack of resources in implementation, e.g., at authorities

or government bodies, which regularly suffer from decreasing budgets (Durant 2017). Furthermore, transparency and responsible governance might take second priority to financial interests (Durant 2017; Gupta and Mason 2014). In addition, the ability and capacities of NGOs or citizens to deal with negative and complex information on environmental quality might be limiting (Durant 2017).

Summary

Environmental transparency refers to the willingness of companies or organizations to make information on environmental performance publicly available. The term implies aspects of communication of information as well as aspects of governance, self-regulation, and control of companies. It is expected to motivate companies to improve their environmental performance to avoid negative impact on reputation (the so-called regulation by revelation approach). If companies opt for environmental transparency strategies, there are voluntary and mandatory types of transparency codes. Even though many companies adopt environmental transparency regimes, the positive expectations are not always met. Failures are caused by lack of resources, priority of financial interests, or lack of capacities of NGOs or citizens.

Environmental movement

Definition

Environmentalism is an ideological, political, and social movement that seeks to protect the natural environment. Environmental social movement organizations focus their actions on saving natural areas, changing lifestyles, promoting an ecological worldview, supporting sustainability policy battles, recycling, replacing environmental inequities with justice, and supporting green consumerism (Haluza-DeLay 2008:205). In various ways, environmentalism tries to lobby for sustainable development and the protection of the natural environment through changes in public policy and individual behavior (Arora 2017). At the core of this movement is the transformation of environmental ideology from anthropocentric to ecocentric, where the human species is only part

of nature (O’Riordan 1981; Pepper 1989). Therefore, environmentalism reflects opposition to the destruction of the natural environment by increasing the rate of economic development and anxiety about the decreasing quality of human existence. Environmentalists note the impact of, i.e., overpopulation and overconsumption as destructive factors. Representatives of this movement are concerned for the impact of problems arisen from industrial development and urbanization, such as resources and waste, pollution on human life. Environmentalist movements are very diverse and represented by a range of organizations, as well as through the actions of individuals.

Environmental Movement

Environmentalism as a complex of social movements first appeared in response to the rapid urbanization, industrialization, and closing of the frontier that launched the Progressive Era in the 1890 (Gottlieb 1993:13). As a modern mass movement, environmentalism began in the 1960s and 1970s. It is worth mentioning that one of the first manifestations of the effort to pay more attention to the environment was the establishment of Earth Day (celebrated annually on April 22). This can be seen as the culmination of an era of protest and as prefiguring the different approaches within contemporary environmentalism (Gottlieb 1993:35). For the first time, Earth Day was organized in 1970 by Wisconsin senator Gaylord Nelson (in September 1995 he was awarded the Presidential Medal of Freedom for his services in this field).

Initially, ecological activities were associated with the negative consequences of the industrial revolution (such as air pollution). The first representatives of environmentalism believed that the government, rather than the free market, needs to protect the environment and provide conservation of resources (Elliott 2018).

The roots of environmentalism can be seen in environmental philosophy and environmental ethics. Environmental philosophy extends the typical boundaries of ethics to the nonhuman

world (► [Environmental Ethic](#)). The first concepts and actions in this area focused mainly on the protection of natural resources. From this perspective, three of them should be identified as pioneering. First concept that highlights the need to conserve resources was created by Gifford Pinchot (1865–1946), the chief of the US Forest Service. The biocentric approach in environmental philosophy was represented by John Muir (1838–1914), founder of the Sierra Club (till now, Sierra Club is one of the most enduring and influential grassroots environmental organization in the United States that fights for Earth's natural resources). An important figure worth mentioning here is also Aldo Leopold (1887–1948), a professor of wildlife management who participated in the designation of the first national wildlife area in America – Gila National Forest in New Mexico (in 1924).

The first publications that initiated modern environmental movement include among others *The Silent Spring* (Carson 1962) and *The limits to Growth* (Meadows et al. 1972). Carson paid particular attention to the role of pesticides and their negative impact on animal and human life. *The Limits to Growth*, a book published by the Roman Club, is analyzing the future of humanity facing the increase in number of inhabitants of the Earth and depletion of natural resources.

In the 1980s, the ecological movement split and radical organizations began to form within. These include Earth First! (which propagates the slogan, “No compromise in the defense of Mother Earth”), Friends of the Earth, and Greenpeace. In their activities they used a range of radical behaviors. Radical environmentalists have shown new interest in deep ecology. In the late 1980s, environmental movements also arose and argued that all people have the right to a safe and healthy environment. The result of their activities was the establishment of an Office of Environmental Justice in 1992. This agency coordinates efforts to address the needs of vulnerable populations by decreasing environmental burdens, increasing environmental benefits, and working collaboratively to build healthy, sustainable communities (Offices of Environmental Justice in Action 2019).

In the 1990s, the actions of the environmental movements focused mainly around problems that could have been solved only by international diplomacy (among others: global warming, acid rain, ozone depletion, biodiversity, and disappearance of rainforests). At that time, in 1987 the Montreal Protocol was finalized (global agreement to protect the stratospheric ozone layer by phasing out the production and consumption of ozone-depleting substances (ODS)) and in 1997 the Kyoto Protocol (international agreement linked to the United Nations Framework Convention on Climate Change, which commits its parties by setting internationally binding emission reduction targets).

As Schnaiberg emphasized (1980), the role of the social structures is very important in the modern world, because through it environment is commodified. Processes such as modernization and industrialization accelerate the use of natural resources. Issues such as global warming, population growth, and the exhaustion of fossil fuel resources are being addressed by environmentalist to the present day. From this perspective, the actions of the environmental movements can be interpreted as a desire to create a sustainable society (► [Managing Change for Sustainability](#)). Although the idea of sustainability often means more than environmental awareness, much of the growth of its popularity can be attributed to the mainstreaming of environmentalism (Tretter 2012:2). Dunlap and Liere (1978) suggested that the rise of environmental movement is linked to the growing acceptance of a new ecological paradigm of worldview (view that human actions have substantial adverse effects on a fragile biosphere).

Environmental behavior can take many forms. Cleveland et al. (2002:293–305) identified six types of pro-environmental behaviors, among them:

- Activist – activities consist mainly in supporting environmental organizations as well as participation in environmental demonstrations. Activists' goal is to influence larger populations.
- Avoider – focus on avoiding products that are harmful to the environment.

- Green consumer – they can be called eco-consumers who believe that buying green products can contribute to solving environmental problems.
- Utility saver – performed any action that minimizes the use of utilities (turning off all lights before leaving home, saving water while washing dishes) to preserve the environment.
- Recycler – made any effort to deal with recycled or recyclable products. This type of behavior might be influenced by social norms.
- Green passenger – are willing to take public transportation and/or reduce the use of passenger vehicles because he/she realizes the negative impact on greenhouse gas emissions on the environment.

Early Environmental Legislation

One of the goals of environmentalists' activities is lobbying for the environment and influencing the law in this area. Over the years, many laws on environmental protection and sustainable development have been enacted. First legal acts related to environmental protection (► [Environmental Law](#)) were the following:

- Clean Air Act (1956) – response to the Great Smoke of London (1952). Numbers of measures to reduce air pollution and the emission of gasses, grit, and dust from chimneys were introduced.
- Sea Birds Preservation Act (1869) – first act to protect wild birds in the United Kingdom. It was designed to reduce the effects of shooting and egg collecting during the breeding season (Barclay-Smith 1959).
- National Environmental Policy Act (NEPA) signed by Richard M. Nixon (in 1970). It states that all federal agencies must conduct a formal process before taking any action that could have a significant impact on the environment. Environmental Protection Agency was created under this law. Its basic task is to conduct research, monitoring, setting standards, and enforcing environmental law (► [Environmental Protection Agencies](#)).

Key-Related Issues

There are several key issues related to environmentalism which should be highlighted. Among them are urban sprawl, renewable energies, sustainable development, and ecological footprint.

Urban sprawl: the process of expanding urban territories to areas with less intensive urbanization, such as suburbs and rural areas, resulting from growing population. It is an uncontrolled process resulting from the demand for new construction and environmentally harmful development practices. Stoel describing this process pointed to a number of environmental consequences. Among them: traffic congestion, air and water pollution (Stoel 1999).

Renewable energies: energy sources, the use of which is not associated with their long-term deficit, because their resource is renewed in a short time (renewable raw materials). Such sources are among others: wind, solar radiation, precipitation, tides, sea waves, geothermal energy, and recycled uranium. The opposite of these are nonrenewable energy sources, i.e., sources whose resources regenerate very slowly or not at all: crude oil, coal, natural gas, and uranium extracted from minerals (► [Energy-Renewable](#)).

Sustainable development: a way of farming in which meeting the needs of the present generation will not reduce the chances of meeting the needs of future generations. In sustainable development, the natural environment is its foundation, economy is considered as a tool, and society's well-being is a goal (► [Sustainable Development](#)).

Ecological footprint: index enabling the estimation of the consumption of natural resources in relation to the possibility of their reproduction by the Earth.

Summary

Environmentalism is the first ideology to be deeply rooted in the natural science; furthermore it cannot be easily located in the left-right ideological spectrum (Cahn and O'Brien 2015). Environmentalism is taking up the problems of

environmental protection, and human's place in the world also emphasizes the interdependencies between human and nature. Bowers and Apffel-Marglin (2005) in their analyses of worsening environmental problems emphasized the role of culture and processes such as modernization and industrialization. In a short period of time, humans impact on the environment decides on the quality of life, and in the longer term, on the survival conditions of human populations. In practice, there are different ways in which environmental concerns are expressed. Stern (1999:82) suggested that all environmental movements have common elements in their beliefs and values – human action has the potential for adversely affecting the biophysical environment, changes in the biophysical environment can harm things people care about, and steps should be taken to avoid at least some harmful actions.

Environmental problems are one of the most important challenges for humanity. In the attempts to solve them, as well as to reduce the negative impact of man on the environment, the role of politics and individual choices is important. Environmentalism has been called the “most enduring and important social movement of the twentieth century” (Andersen and Thiele 2000). In the history of environmentalism and environmental movements, there were many events that can be called milestones. Environmentalists could be related to the number of significant accomplishments. According to Earth Day Network the fight for a clean environment continues with increasing urgency, as the ravages of climate change become more apparent every day (www.earthday.org/history/).

It should also be indicated that the achievements and leadership of grassroots environmental activists from around the world are honored by various awards. One of them is the Goldman Environmental Prize. In 1990 Richard and Rhoda Goldman, marriage of philanthropists, established this Prize as a way to demonstrate the international nature of environmental problems. In 1990 Richard and Rhonda Goldman, marriage of philanthropists, established this Prize as a way to demonstrate the international nature of environmental problems and reward

individual efforts to protect the environment. (see <https://www.goldmanprize.org/>).

Definition

Several fields of study engaged with the concept of equality of opportunity (EO), such as philosophy, political theory, ethics, and law.

Despite the different conceptions and approaches flourished on EO, the core shared meaning concerns the idea that individuals should have equal prospects for developing their life. This deals with outcome distributions of various types, such as economic capital and work positions, forms of social capital such as social networks and affiliation, and forms of cultural capital such as education (e.g., Lynch & Baker, 2005).

A state of EO corresponds to the absence of circumstances (such as family socioeconomic and cultural background, ethnic origin, gender, age, etc.) and related barriers, prejudices, or preferences that influence individual achievements. Thus, different outcomes achieved by people are justified only on their personal choices, efforts, skills, and competencies. Hence, the only disparities in an equitable society are due to individual decisions.

Introduction

An equal society has more possibilities to prosper (e.g., World Bank, 2006). Indeed, exogenous factors on the individual income and employment prospects reduce the chances of growth. Furthermore, persistent inequalities in the initial opportunities constitute traps that prevent certain population groups' participation in economic activity and are disadvantageous for growth.

Accordingly, since the mid-1970s, the European Union and numerous governments have undertaken policies supporting EO. Then, several private and public organizations, universities, and colleges have imitated them (Brine, 1995).

Although EO is closely related to the concepts of equity, justice, and fairness, they are not synonymous. Indeed, while the latter concepts rely upon a normative criterion defining what is equitable, just, and fair, the concept of EO refers to people holding an identical status (or similarly having equal conditions); hence it does not necessarily imply equality. In this regard, the concept of vertical equity requires different treatments for individuals with peculiar characteristics.

Consequently, inequalities related to circumstances beyond an individual's control should be eliminated or compensated for by public intervention (e.g., Peragine & Biagi, 2019).

EO encompasses several concepts (Bagirole, 1997). Formal EO is the absence of direct (unfair) discrimination. Therefore, any deliberate discrimination must be relevant and meritocratic. For example, job interviews should only discriminate against applicants on the grounds of their job competences.

Substantial EO is the absence of indirect discrimination. It requires society to be fair and meritocratic. For example, no one should drop out of school for economic reasons.

Formal EO does not imply substantive EO. Firing every employee who gets pregnant is formally equal, but in substance it harms women more.

In this sense, the discourse on EO has recently joined that of diversity and inclusion policies aimed at compensative actions (sometimes called positive actions, e.g., Galizzi & Siboni, 2016). These are interventions undertaken mainly in the workplace and by educational institutions. They aim to remove barriers and contrast past discrimination suffered by specific groups (such as ethnic minorities, women, and the disabled), as well as to enhance management performance and research by increasing diversity in human resources and students (e.g., Healy & Noon, 2010).

Accordingly, several policies have been promoted both by European Union and by member states to protect the human rights of people with disabilities and support disability management practices by organizations. Such policies discard the perspective of the medical model that understands disability as a disease, conceiving it instead as a social relationship that involves the characteristics of people and the environment based on the bio-psychosocial model.

The policy of equality in opportunity of employment adopted by the European Personnel Selection Office is also part of this line. It aims to increase the diversity of its talent pool and help European Civil Service be fully representative of the diversity of the European citizens it serves.

Approaches to EO

Several approaches have been implemented for EO policies (e.g., Brine, 1995).

According to Welfarist Economics, EO emerged to address the limits of the principle of efficiency of markets by proposing an approach aiming at a distributional justice criterion. This approach highlights the potential trade-offs between equity and efficiency, which socioeconomic policies often focus on. For instance, tax reforms are often biased on equity at the expense of efficiency, while the trade-off could be solved by defining specific social welfare criteria (Peragine & Biagi, 2019).

The Welfarist approach is based on measuring individual achievements to justify welfare measures. However, it does not provide information on the fairness of the process by which individuals attain a certain economic and social status. Hence, the concept of EO has been introduced to go beyond the analysis of (in)equality of outcomes (income, health, education, etc.), approaching the definition of "opportunities" as the relevant space to design social policies. The fairness of a given distribution does not derive from the outcomes resulting from that distribution but rather from the consequences derived from the sets of choices that individuals can undertake. A given economic and social status distribution can be considered fair if individuals achieve the result on a level-playing field and comply with the rules. Furthermore, in the debate over the last decades, many political philosophers have added that a society could be considered equitable if opportunities are equally distributed rather than outcomes (e.g., Dworkin, 1981; Cohen, 1989; Arneson, 1989).

Accordingly, in a society, disparities in outcome distribution if generated by personal choices are less blameworthy than those caused by predetermined factors over the control of individuals.

This highlights the role of individual responsibility in evaluating social arrangements, acting as an incentive for individuals to exert more effort. Also, support for redistribution policies increases when people believe that existing inequalities are due to unequal opportunities.

Since the 1990s, the economic literature has intensely engaged in developing frameworks to capture each specification of the EO concept.

Both individual responsibility and the source of inequality in the assessment of social states have motivated several declinations of EO (Peragine & Biagi, 2019). In particular, two competing principles have been identified at the core of the Egalitarian approach of EO. The first (principle of compensation) maintains that society has to compensate for unfair differences in individual outcomes when caused by differences in circumstances. The second (principle of reward) suggests that inequalities in outcomes due to different efforts experienced by people are equitable and should not be compensated.

According to Lynch and Baker (2005), EO corresponds to the equality of condition. Equality of condition implies empowering individuals to assure them similar real options to live a good life. Specifically, equality of conditions is expressed through five key dimensions, which are autonomous but refer to each other. The first dimension concerns resources: economic, social, cultural, and environmental assets as well as time and health care resources. The second dimension is that of respect and recognition, which concerns acceptance of the fact that each individual enjoys the rights and privileges related to citizenship in the country where he or she lives and openness to a critical dialogue on differences. The third dimension concerns love, care, and solidarity; being cared for is a prerequisite for adequate human development, and societies should be arranged to facilitate it. For instance, the education system can support people educated about care and solidarity relations, and employment, transportation, and neighborhoods should be structured to facilitate caring for vulnerable people. The fourth dimension related to power; traditional liberal civil and political rights with a more egalitarian, participatory politics and the extension of democratic principles to all areas of society, particularly the economy and the family, reduce inequalities. The last dimension, working and learning, implies that everyone has the right to access potentially satisfying work. There should be limits to the imbalance in work burdens, and people should be

compensated for unequal burdens. All kinds of work should be considered, both paid and unpaid, including familiar caregivers and solidarity. At the same time, equality in learning should ensure that everyone has engaging and satisfying learning to assure human development.

Insights into the European Union Discourse of EO

The Treaty of Rome (1957), which established the European Economic Community, in Article 119, states that men and women must receive equal pay for the same work, hence the request to member states to adopt legislation to guarantee no work discrimination based on sex. It also introduced a broader debate on EO considering the egalitarian democratic aspirations of Western liberal democracy. Specifically, Europe is committed to equal opportunities and equality of treatment for people regardless of gender. In fact, it develops measures to pursue “gender mainstreaming” in all areas of economic, social, cultural, and family life. According to European Commission (2005, p. 5), “Gender mainstreaming is a tool to better understand the causes of inequalities between women and men in our societies and come up with appropriate strategies to tackle them. The goal is to achieve equality between women and men.”

After becoming the European Union (1992), in 1997, the Treaty of Amsterdam gave it new competencies and strengthened the principle of nondiscrimination. Then, the fight against discrimination promoted by Europe has gone beyond gender, also addressing those related to race and ethnic origin, religious belief, disability, age, and sexual orientation. As a result, the European Union’s commitment to equal opportunities and nondiscrimination is present in all its policies, including those aimed at promoting regional development.

According to Brine (1995), the development of the discourse on EO in the European Union advanced in three main ways: first, approving several Action Programs for the Equal Opportunities of Women, giving the understanding of

European intention behind legislation and policy, and providing a statement of priorities for action and funding; second, establishing an Equal Opportunities Unit to produce and evaluate the Action programs on EO; and third, introducing the European Social Fund, the structural fund aimed at supporting workers' vocational training and retraining.

Concerning interventions in gender equality over the last decades, the European Union has set up equal treatment legislation, gender mainstreaming, integration of the gender perspective into all other policies, and specific measures for the advancement of women. These interventions have made significant progress, such as the increasing number of employed women and accessing better education and training. Despite this, gender gaps remain. In the labor market, women are still overrepresented in lower-paid sectors and underrepresented in decision-making positions, with severe vertical and horizontal segregation phenomenon particularly in academia, science, and technology fields (e.g., EC, 2021; Siboni et al., 2016).

Moreover, since 2016, the European Institute for Gender Equality (EIGE) has been established as a European Union-initiated body dedicated exclusively to gender equality. Under EIGE, the Gender Equality Index has been formulated and is annually published as a key benchmark for gender equality in European countries.

Among the initiatives and strategies on equality, diversity, and inclusion, recently the European Commission adopted the Strategy for Gender Equality 2020–2025 (EC, 2020). This Strategy aims to eliminate in Europe gender-based violence, sexual discrimination, and structural inequality between women and men and establish equality between women and men, girls and boys, in all their diversity. The Strategy is structured around six themes: freeing from violence and stereotypes; thriving in a gender-equal economy; leading equally throughout society; gender mainstreaming and an intersectional perspective in European Union policies; financially supporting actions in gender equality in the EU; and addressing gender equality and women's empowerment across the world. Implementation

of the Strategy presupposes a dual approach that combines gender mainstreaming with specific targeted actions to achieve gender equality. Notably, this initiative is innovative in introducing and integrating the intersectional perspective. The intersectional approach focuses on the experiences of discrimination arising from the intersection between sex and gender with other characteristics pertaining to personal identity (such as colour, ethnic origin, religious belief, and disability) (EIGE, 2022).

Summary

EO embraces a wide range of concepts, definitions, and interventions.

While formal EO, such as the absence of direct discrimination, is established by law and codes of ethics, these can do nothing against indirect discrimination. Thus, substantial EO requires interventions and actions to remove barriers and contrast discrimination in workplace, education, economic life, and society. Sometimes it involves the use of affirmative actions (or positive actions), policies aimed at giving a specific advantage to an under-represented group (e.g., women, the disabled, ethnic minorities), for instance by adopting targeted training opportunities or a targeted redistribution of resources, in order to correct a situation of inequality. These actions imply, on the other hand, that the group favoured by the situation of inequality to be corrected suffers a disadvantage. In a sense, the pursuit of substantial EO shifts the “starting point” further back in time. Consequently, the EO enriches its meaning, aims, and tools combining with the concepts of diversity and inclusion.

This work outlines origins and definition of EO, different approaches to EO, and provides an insight to the European policy and strategy on EO.

Equator Principles

Jianghong Liu

London Metropolitan University, London, UK

Definition

The Equator Principles (EP) is a risk management framework and common financing criteria, incorporated by financial institutions, for determining, assessing and managing environmental and social risks when financing projects. It aims to provide a standard benchmark for due diligence and monitoring procedure to support social and environmental risk decision-making. The framework ensures that the projects that the financial institutions supports are operating in accordance with social and environmental friendly standards. The EP “apply globally, to all industry sectors and to five financial products: (1) Project Finance Advisory Services; (2) Project Finance; (3) Project-Related Corporate Loans; (4) Bridge Loans and (5) Project-Related Refinance, and Project-Related Acquisition Finance” (The Equator Principles Association 2023, p.1). The EP is reviewed and revised periodically in order to adopt the ongoing learning practices and evolving

changes. The fourth Equator Principles (the newest version, EP4) was released in November 2019 and came into effect on 1 October 2020.

Introduction

As of March 2023, 138 Equator Principles Financial Institutions (EPFIs) in 38 countries have officially adopted the Equator Principles, known as the EP members, offering the majority of international project finance in emerging and developed financial markets. All members must comply the EP standards in the process of managing social and environmental risk when financing projects. What's more, the Equator Principles Association provides governance rules for EPFIs to follow up in the process of managing, administering and developing the EP and the EP association. In particular, the EP governance document specifies the rules of unincorporated association.

Equator Principles Financial Institutions (EPFIs) are committed to implementing the EP in internal social and environmental policies, procedures and standards for financing projects and will not provide Project Finance (or other four financial products) to projects where the client will not, or is unable to, comply with the Equator Principles (The Equator Principles Association 2023). While the Equator Principles are not intended to be applied retroactively, the EPFIs will apply the ten equator principles to the financing of expansion or upgrade of an existing project (The Equator Principles Associations 2023). Mandated EPFIs are expected to share relevant environmental and social information with other mandated firms to achieve the goals made by the Equator Principles Association. In addition, EPFIs acknowledge the application of the EP could make contribution to achieve the objectives of the United Nations Sustainable Development Goals (SDGs).

Nowadays, the Equator Principles have gradually increased the attention on social standards and responsibility.

The Equator Principles have fulfilled their responsibility to human rights in line with the

United Nations Guiding Principles (UNGPs) on Business and Human Rights by implementing human rights due diligence. They also recognised that their members play a significant role in the objectives of the 2015 Paris Agreement, such as the application in the recommendations of the Task Force on Climate-related Financial Disclosures (TCFD) under the Equator Principles. The EP Association provides a platform to engage with a broad range of stakeholders, including non-governmental organisations (NGOs), clients, and industry bodies. More important, the EPs provide guidance to support members in developing their own Environmental and Social Risk Management Systems.

The Ten Equator Principles

Principle 1: Review and Categorisation

Principle 2: Environmental and Social Assessment

Principle 3: Applicable Environmental and Social Standards

Principle 4: Environmental and Social Management System and Equator Principles Action Plan

Principle 5: Stakeholder Engagement

Principle 6: Grievance Mechanism

Principle 7: Independent Review

Principle 8: Covenants

Principle 9: Independent Monitoring and Reporting

Principle 10: Reporting and Transparency

Summary

The Equator Principles is a baseline and provides framework for developing individual, internal environmental and social policies and procedures. The Equator Principles do not create any rights in, or liability to, any person, public or private. Financial institutions adopt and implement the Equator Principles voluntarily and independently, without reliance on or recourse to the International Finance Corporation, the World Bank Group, the Equator Principles Association,

or other EPFIs (The Equator Principles Association 2023). In a situation where there would be a clear conflict between applicable laws and regulations and requirements set out in the Equator Principles including confidentiality obligations, the laws and regulations of the relevant host country shall prevail (The Equator Principles Association 2023). Since the release of EPs in 2003, some scholars have assessed the voluntary approach of the EPs (Missbach 2004; Richardsons 2005; Wright and Rwabizambuga 2006; Scholtens and Dam 2007; Macve and Chen 2010; Conley and Williams 2011). Some EPs members have adopted the 10 principles, but certain levels of concerns on the integrity (e.g., bank lobby issues) still exist. The monitoring procedure on these EPs mandate banks still needs more improvements.

Ethic of Love

Dyann Ross
School of Social Science, University of the
Sunshine Coast, Sippy Downs, QLD, Australia

Synonyms

Anti-oppressive ethics; Justice ethics; Social justice; Social precautionary principle; Social sustainability

Definition

Business ethics as a field in the broader area of philosophy recognizes the moral nature of corporations, managers, and shareholders as inseparable from the operations of the business (Moriarty 2017). There is an inconclusive debate in the literature as to whether a corporate entity can be morally responsible or whether it is to be located in the employees and stakeholders (French 1979; Friedman 2007). The Rawlsian (1971) idea of justice as fairness and virtues ethics theory (Hartman 2015) as desirable qualities of character are used to recommend the adoption of an ethic of love. An ethic of love that is fair and caring is particularly relevant for businesses where there is contestation with other stakeholders about the corporation's responsibilities. As such it regards both the corporate entity and the people who act on behalf of the corporation as having moral responsibilities, albeit that these might involve different orders of legal and moral accountability. An ethic of love extends on the Rawlsian notion of justice to address this moral issue of corporate entity and actors' moral responsibility. It extends conventional business ethics to situate love and justice as the interlinked moral baseline for business (Brueckner and Ross 2020).

Western philosophy identifies several forms of love such as eros – romantic love; philia – friendship and shared goodwill; agape – parental love and an altruistic love for strangers, animals,

and nature, and; storge – love of family and community. Love is understood by some of the greatest leaders for social change as a powerful and potentially transformative resource that can unite people for nonviolent struggles across boundaries of politics, economic systems, class, culture, and country (Gandhi 2013; King 1957; Mandela 2013).

Love is more than a feeling, rather it comprises actions as ethical and political capacities that are crucial for socio-ecological justice work (Godden 2017). hooks (1994) explains that the ethic of love brings people to an increased concern for issues of domination and injustice and a desire to understand and challenge the interconnected nature of systems of domination. Elsewhere hooks (2001) explains that an ethic of love requires the demonstration of care, respect, knowledge, and responsibility in situations of conflict and violence.

Introduction

Landes (2020) identifies the area of adversarial ethics that derives from a concern about the limited moral premise of the desirability of competition which is inherent capitalist logic. He explains that “adversarial contexts, although genuinely specific in nature, do not justify as much departure from common morality than it is often assumed” (Landes 2020, p. 1). Adversarial ethics suggests that parties in competition or conflict in the business context should be subject to some moral strictures to discourage harmful or deceptive behavior (Landes 2020). The love ethic bridges the interests and differences between competing or conflicting stakeholders and engages the power disparities to gauge the proper order of responsibilities of the stakeholders. Stakeholder theory in business (Freeman 2010) gives credence to regarding all interested and impacted parties being regarded as legitimate actors in conflict situations. It is thus not sufficient for corporations to regard their moral responsibility as being only to make profits for the shareholders.

In terms of sustainable development, a love ethic involves seeking justice for adversely

impacted stakeholders where there is a failure of corporate social responsibility (CSR) by a business entity (Ross 2017a, 2020a). It comprises concerted actions based on socio-ecological justice (White 2009, 2017), social sustainability, and the social precautionary principle. Socio-ecological justice refers to actions to address social injuries, environmental harm, and harm to nonhuman animals caused by development (Ross 2020b). Social sustainability is not possible without socio-ecological justice and brings attention to the human costs and impacts of development (O’Faircheallaigh 2013; Tester 2013). The social precautionary principle needs to be considered alongside environmental precautions to ensure no harm is done to humans and nonhuman animals. The social precautionary principle is an extension on the Rio Declaration of 1992 in relation to environmental precautionary principle (United Nations Global Compact 2020).

The love ethic encompasses all forms of love where the defining features they have in common being the presence of care, nonviolence, and fairness in relationships. The language of love can be controversial and has many contested meanings. For present purposes it is to be noted that the idea of love as eros is often reduced to love as sex and this reductionist thinking is unhelpful for justice work. This is not to say love as a romantic attachment has no place in justice struggles, as deep ecologists (Macy 2019) argue people need to be “in love” with the planet to sustain the work that is needed.

It is important to understand love as a political capacity which is necessary for justice work to ensure a deep connection with the dignity, rights, and equal moral worth of oppressed groups. Without this deep loving connection and engagement, it is easier to justify tyrannical actions or to blame people for causing their unjust situations (Nussbaum 2013). Further, a love ethic needs to be interlinked with trans species equality to avoid species domination by humans (Braidotti 2013). Trans species equality challenges anthropocentrism which rests on a dualism between the superiority of humans and the exploitation and use of nonhuman animals, other sentient beings, and planet earth (White 2018).

The means and ends of socio-ecological justice work become closely aligned when guided by an ethic of love. The idea of adversely impacted activist stakeholders walking the talk of anti-oppressive ethics and theories is central to justice work. An anti-oppressive approach recognizes that violence cannot be used in the name of a loving ethics. The purpose of socio-ecological justice work is to challenge and resist harm and unfairness. The International Federation of Social Workers (2018) argues that violence can be addressed by challenging negative discrimination; recognizing diversity; distributing resources equitably; challenging unjust policies and practices; and working in solidarity to enable social inclusion. One implication is that in an ecological conflict situation, discrimination or violence against protesters (Poulos and Haddad 2016) cannot be challenged by reversing the discrimination or violence toward the powerful actors (e.g., businesses, governments, financiers) by the powerless social groups (e.g., adversely impacted stakeholders, including animals and the environment). Efforts to obtain accountability for harm need to be nonviolent. That is, justice work needs to invite cooperation by appealing to the moral good in the stakeholders. It is not about the use of force, threats, or violence (King 1999) as this would be morally incongruent. But neither is it a matter of capitulating to the harm caused by economic and species inequality and the unchecked plunder of a business-as-usual approach by, for example, many multinational business entities (Conde 2017).

The key aim in social justice struggles in the business sector is to achieve accountability for violence and harm done as a result of the business operations. When the business entities responsible for social injury and environmental harm decline invitations to problem-solve the issues and to be accountable, an ethic of love can guide activist stakeholders’ next steps (Ross 2020a, b). Gandhi’s values-based leadership in India’s independence struggle was guided by Ahimsa, the Hindu term for love (Gandhi 2013). Central to Gandhi’s leadership approach was the moral integrity derived from modeling love and nonviolence in his personal life and public work

(DiSalvo 2013). Martin Luther King (1957) was influenced by Gandhi's work and he believed that justice for black people in America was to be sought by the appeal to moral force not the use of violence.

Struggles for environmental justice and sustainability stand in this tradition of nonviolent, grassroots campaigns utilizing people power. Research shows that justice struggles that avoid violence, build on community strengths and needs, and listen to the wisdom of the people during the conflict are more successful in achieving social change (Chenoweth and Stephan 2011). For example, Ross and Puccio (2020) describe an interlinked set of challenging and resistive strategies, focused on holding the government accountable for not providing public safety and protection. As part of long-term, home grown community activism, the local resident's activist group lobbied the state government. This involved providing evidence and appeals to the government in relation to pollution from a multinational mining company and the breaching of its licensing obligations. All the strategies are nonviolent, working within the policies and consultation processes of government. Other initiatives have also been undertaken when government and industry, for example, failed to undertake independent air monitoring around the alumina refinery. The independent bucket brigade was a local resourced effort to obtain air samples using airtight buckets during pollution events that could be analyzed by an independent source, to support community claims of harm (Community Alliance for Positive Solutions, CAPS 2020).

The Sustainability Issue

There is an international groundswell occurring with natural resource extraction industries and agri-businesses at the center of an increasing number of ecological conflicts with activist groups (see examples in Ross et al. 2020). This is because these types of industries use the environment and nonhuman animals as part of their wealth creation. Research has shown that people will tend to resist industry in their localities when they perceive it as

a threat to their safety, social amenities, ecosystems, and cultures (Pedersen 2014).

Conflicts with adversely impacted stakeholder groups can be unwelcome and very costly to a corporation's public image and "social license to operate" (Trebeck 2008, p. 353). In recent decades there has been an international recognition of the importance of linking the economic aspects of business with environmental and social factors. The language of achieving this triple bottom line (Elkington 1997) as part of good business practices has provided a leverage point for environmental victim activism (White 2009) to question and challenge unsustainable and unjust operations. CSR is a phrase used by businesses to articulate how they are acting to add a social value to their profit-driven entities (Models of Success and Sustainability, MOSS 2015). CSR is a top down, industry defined, and controlled set of public statements relating to a commitment by businesses to act in a socially responsible manner toward their shareholders and host community (MMSD 2002). Moriarty describes CSR as:

Actions by businesses that are (i) not legally required, and (ii) intended to benefit parties other than the corporation (where benefits to the corporation are understood in terms of return on equity, return on assets, or some other measure of financial performance). (2017, n.p.)

Typically, though, CSR is limited to philanthropic gestures in local communities with little acknowledgment of inconsistencies between words, image, and actions (Ross 2017b). For example, in 2008 BHP Billiton was accused of corporate irresponsibility due to the failure to remedy ongoing contamination at a copper oxide plant in Tintaya, Peru (Anguelovski 2008). Just 2 years prior when this issue was occurring, the Western Australian Chamber of Commerce and Industry (2006) praised BHP Billiton for its substantial contribution to health, safety, and sustainability.

The issue for sustainability managers and activists seeking socio-ecological justice is that to date, no amount of well-organized, love ethic informed and nonviolent strategies has shifted the global balance of power toward sustainable

industries, communities, and landscapes. Even so, some collective capacity has been achieved by the linking up of resistance efforts by similarly impacted groups. Some examples of activism are: “Shut the Gate” in Australia to support farmers resisting fracking on their properties which have been greatly assisted by social media campaigns; calls for public inquiries into industry pollution; and class legal action into water contamination from fire retardant chemical pollution at Australian military bases. People power in a range of forms across many different countries, and situations provide many examples and clues for how to mount successful challenges to unsustainable and unjust business operations in specific contexts (Brueckner and Sinclair 2020).

The flow on issue is that the significance of often hard won successes may not be recognized due to the backlash from industry interests, including the media and by elites such as climate change naysayers. For example, threats of job cuts (Alcoa and Western Australian port workers strike) or jobs not eventuating (Adani coal development in Queensland) and removal of financial support to communities and local governments (Alcoa in relation to Yarloop after a major bush-fire) can be severe and depleting of the confidence of people to stand up for justice. To counter this push back from big business and the elites, there is a need to ensure the lessons and achievements of the justice work are not lost and are shared on to other eco-justice activist groups as needed. Further, the challenge for activist groups and their supporters is maintaining hope in the struggles that often do not have quick solutions or a clear win for the people and the environment. An abiding belief in the power of nonviolence and love to address complex human-made problems can sustain this hope.

An Ethic of Love Model for Sustainable Development

The significance of an ethic of love in environmental justice work is evident in the area of community work for transformational change

and sustainable structural change. Godden (2018) describes how a love framework guided research with community workers in Timor-Leste. The coresearcher collaborative inquiry created the following statement of their love guided practice:

Domin mak hanesan hahalok nebe ita hatudu liu husi manera oi-oin hodi ema seluk bele sente ho diak: liberdade, demokrasia, toleransia, moris, adaptasaun, unidade no felisidade [Love is actions that we show through a variety of ways so that other people feel freedom, democracy, tolerance, alive, adaptation, unity and happiness]. (Godden 2018, p. 90)

A love ethic can provide practical guidelines for sustainability managers and activists irrespective of the particularities of each situation where sustainability is under threat. Ross (2017a) describes a principles-based model that articulates the responsibilities of key stakeholders according to one of three interlinked principles. Thus, in situations of ecological conflict, the government, who is the regulator of industry, has the responsibility to enact the social precautionary principle. This is to occur out of deference to the wisdom of the people impacted by the industry’s operations. The industry entity needs to enact social (and other forms of) sustainability relevant to the issues in the conflict. The impacted stakeholders have a responsibility to seek social justice by speaking up, assisting in establishing evidence of adverse impacts and by contributing to identifying a just outcome (Ross 2017a).

All three parties meet to undertake respectful, power-equalized, and evidence-based discussions and negotiations. The outcomes sought from these nonexploitative dialogues are government accountability to its people; corporate social sustainability in addressing the substance of the conflict; and justice for the impacted stakeholders (Ross 2017a, 2020a). Failures of responsibility by the government and/or the corporation will be failures of moral integrity of the leaders of each constituency. A robust and loving appeal to act with moral integrity will allow a discernment of the practical actions needed in what is usually a contested complexity of issues, agendas, and solutions. It is always the preserve of justice

activists to resist: dominant, self-serving constructions of the issue; being positioned as the problem; and having no choice but to accept the status quo or inadequate solutions being offered.

A love ethic in situations of intractability by the powerful entities involves a resistance to unsustainability and injustice at every opportunity. Gandhi believed that “underserved suffering touches the heart and mind of even the oppressor” (DiSalvo 2013 p. 138). He also recognized the limits of litigation and appeals to the laws of the land when these same laws are designed to protect the interests of the elites of society. Resistance must be nonviolent but can match the power of the dominant groups who are committing environmental crime and causing social injuries. The idea of active resistance is based on people’s right to defend and protect their lives, livelihoods, and homelands. It can take many forms such as noncooperation with unjust laws and harmful practices; nonviolent civil disobedience; protests; strikes; and campaigns (Sharp 2012).

Summary

An ethic of love can guide stakeholders toward just and sustainable processes and outcomes in situations of ecological conflict between businesses and communities. Love is a contested idea and its use in ecological conflict situations is not widely accepted. Nevertheless, it does provide an ethical approach that builds on a long tradition of nonviolent social movements for justice, peace, and environmental protection. The adaptation of an ethic of love based on research with stakeholders in a community/industry conflict in Australia identifies three key principles for sustainable management. These principles are social justice; the social precautionary principle; and social sustainability. Sustainability efforts guided by these principles will ensure the means and ends are aligned. Violence cannot create justice and sustainability. An ethic of love opens up spaces between stakeholders to practice sustainability in their interactions and negotiations.

Hope is anchored in small steps forward and acts of good will in challenging situations.

Ethical Absolutism vs. Ethical Relativism

Definition

Ethical absolutism and ethical relativism are positions in ethics about the existence of objective values and intrinsically moral acts. Ethical absolutism is a position which argues for the existence of objective values and intrinsically moral acts. As such there can exist moral principles which are always valid and correct. Ethical relativism is a position that holds that moral values are relative to some further instance.

Ethical Absolutism

There seem to be moral principles which humans hold intuitively valid and correct. For example, various formulations of the “golden rule,” the gist of it being that we should treat others as we would want to be treated. This idea can be found in many moral and religious teachings. Moreover, it seems that people regardless of culture or any other factor hold this, and similar, principles and their fundamental values as true and valid. Moral absolutism is an ethical position where it is argued that moral principles, values, and rules which are always true exist. Ethical absolutism also implies that actions are intrinsically right or wrong. An excellent example of absolutism in ethics can be found in the deontological theory of a German philosopher Immanuel Kant and his idea of the categorical imperative. Actions which can pass the test of the categorical imperative should be followed in every situation, no matter the specific consequences. Christianity may serve as another example, God’s commandments are considered always valid and are expected to be obeyed.

Ethical Relativism

Although different position than ethical absolutism, ethical relativism is also supported by many examples from contemporary and historical experience. For example, already in primary school children can catch a glimpse that what we think about stealing, lying, or slavery was not always the same everywhere in the world or every point in history. There were times when slavery was just a fact of life, accepted and considered normal. Also, children very early on become aware that some practices which are considered in our society to be morally unacceptable today might be acceptable and present in some other society at the same time. Ethical relativism is a position which takes those examples into account stating that moral principles are relative to different factors and there are no objective values as such nor are there intrinsically right or wrong actions.

In ethics, several types of ethical relativism exist depending on the factors in focus which contribute to moral values being relative (Baghrmian and Carter 2018). For example, cultural relativism will simply descriptively take into account that people in different cultures judge actions differently. Descriptive relativism, simply put, describes that there are differences in moral beliefs and principles from culture to culture and something which is encouraged in one may be sanctioned in the other. It is essential to add that in descriptive relativism, it is not only about differences in ethical judgments but in the basic principles themselves (Frankena 1973, p. 109). Both cultural and descriptive relativism look at cultural diversity and as such draw heavily from disciplines such as cultural anthropology.
